

Chapter 7

Operators on Inner Product Spaces

Comment: at some point in this chapter I start to use phrase like “think of a matrix A as an operator” as a short form of “suppose $T \in \mathcal{L}(V)$ is such that $\mathcal{M}(T) = A$, with matrix evaluated with respect to the standard basis.”

7A Self-Adjoint and Normal Operators

1 Suppose n is a positive integer. Define $T \in \mathcal{L}(\mathbb{F}^n)$ by

$$T(z_1, \dots, z_n) = (0, z_1, \dots, z_{n-1}).$$

Find a formula for $T^*(z_1, \dots, z_n)$.

Solution:

Suppose $(z_1, \dots, z_n), (w_1, \dots, w_n) \in \mathbb{F}^n$. Then

$$\begin{aligned}\langle T(z_1, \dots, z_n), (w_1, \dots, w_n) \rangle &= \langle (0, z_1, \dots, z_{n-1}), (w_1, w_2, \dots, w_n) \rangle \\ &= z_1 w_2 + z_2 w_3 + \dots + z_{n-1} w_n \\ &= \langle (z_1, \dots, z_n), (w_2, \dots, w_n, 0) \rangle\end{aligned}$$

By the definition of the adjoint, we must have

$$T^*(w_1, \dots, w_n) = (w_2, \dots, w_{n-1}, 0),$$

which is the sought formula for the adjoint. \square

2 Suppose $T \in \mathcal{L}(V, W)$. Prove that

$$T = 0 \iff T^* = 0 \iff T^*T = 0 \iff TT^* = 0.$$

Solution:

First equivalence is just the property of a zero map. Indeed, for any $v \in V$, $u \in W$:

$$\langle 0v, u \rangle = 0 = \langle v, 0u \rangle.$$

That is, zero map is “self-adjoint” (although these maps are from different vector spaces).

Third equation follows directly from the second:

$$T^* = 0 \Rightarrow T^*(Tv) = 0 \text{ for every } v \in V \Rightarrow T^*T = 0.$$

Similarly, $T = 0 \Rightarrow TT^* = 0$.

Now suppose $T^*T = 0$. That means for every $v \in V$:

$$\langle T^*Tv, v \rangle = \langle 0, v \rangle = 0$$

and also

$$\langle T^*Tv, v \rangle = \langle Tv, Tv \rangle = \|Tv\|^2 = 0$$

By the definiteness property of the inner product, $Tv = 0$ for every $v \in V$. Hence $T = 0$.

Similarly, $TT^* = 0$ implies that $T^* = 0$.

Established relations are sufficient to get from any of the stated equations to any other, as desired. \square

3 Suppose $T \in \mathcal{L}(V)$ and $\lambda \in \mathbb{F}$. Prove that

$$\lambda \text{ is an eigenvalue of } T \iff \bar{\lambda} \text{ is an eigenvalue of } T^*.$$

Solution:

Suppose λ is an eigenvalue of T with a corresponding eigenvector v . That means $(T - \lambda I)$ is not injective, i.e. dimension of its null space is greater than zero. Using properties of adjoint (7.6) and corollary 6.51, we see that

$$\begin{aligned} \dim \text{range}(T^* - \bar{\lambda}I) &= \dim V - \dim (\text{range}(T^* - \bar{\lambda}I))^\perp \\ &= \dim V - \dim (\text{range}(T - \lambda I)^*)^\perp \\ &= \dim V - \dim \text{null}(T - \lambda I) \\ &< \dim V \end{aligned}$$

The last inequality implies that $(T^* - \bar{\lambda}I)$ is not injective (Theorem 3.22), which implies that $\bar{\lambda}$ is an eigenvalue of T^* (Theorem 5.7). \square

4 Suppose $T \in \mathcal{L}(V)$ and U is a subspace of V . Prove that

$$U \text{ is invariant under } T \iff U^\perp \text{ is invariant under } T^*.$$

Solution:

Suppose $u \in U$ and $v \in U^\perp$, U is invariant under T . We have

$$\begin{aligned} \langle Tu, v \rangle &= 0 \\ \langle Tu, v \rangle &= \langle u, T^*v \rangle \end{aligned}$$

This means $\langle u, T^*v \rangle = 0$ for every choice of u and v . Therefore, $T^*v \in U^\perp$ for every $v \in U^\perp$, hence, U^\perp is invariant under T^* . Changing T to T^* and U to U^\perp gives proof in other direction. \square

5 Suppose $T \in \mathcal{L}(V, W)$. Suppose e_1, \dots, e_n is an orthonormal basis of V and f_1, \dots, f_m is an orthonormal basis of W . Prove that

$$\|Te_1\|^2 + \dots + \|Te_n\|^2 = \|T^*f_1\|^2 + \dots + \|T^*f_m\|^2.$$

Solution:

Denote a matrix of T with respect to the bases e_1, \dots, e_n and f_1, \dots, f_m by A . Matrix of T^* is then A^* (Theorem 7.9).

Note that $\|Te_j\|^2$ equals sum of elements of the first row of A squared. Similarly, for other vectors e_j . Thus:

$$\|Te_1\|^2 + \cdots + \|Te_n\|^2 = \sum_{k=1}^n |A_{k,1}|^2 + \cdots + \sum_{k=1}^n |A_{k,n}|^2 = \sum_{j=1}^m \sum_{k=1}^n |A_{k,j}|^2.$$

For T^* we have:

$$\|T^*f_1\|^2 + \cdots + \|T^*f_m\|^2 = \sum_{j=1}^m |A_{j,1}^*|^2 + \cdots + \sum_{j=1}^m |A_{j,n}^*|^2 = \sum_{k=1}^n \sum_{j=1}^m |A_{j,k}^*|^2.$$

By definition of conjugate transpose:

$$\sum_{k=1}^n \sum_{j=1}^m |A_{j,k}^*|^2 = \sum_{k=1}^n \sum_{j=1}^m |\overline{A_{k,j}}|^2 = \sum_{k=1}^n \sum_{j=1}^m |A_{k,j}|^2,$$

thus leading to the desired equality. \square

6 Suppose $T \in \mathcal{L}(V, W)$. Prove that

- (a) T is injective $\iff T^*$ is surjective;
- (b) T is surjective $\iff T^*$ is injective.

Solution:

(a) We have:

$$\begin{aligned} T \text{ is injective} &\iff \dim \text{null } T = 0 \\ &\iff \dim (\text{range } T^*)^\perp = 0 \\ &\iff \text{range } T^* = W \\ &\iff T^* \text{ is surjective.} \end{aligned}$$

Here we used Theorem 3.15 for the first equivalence, Property 7.6 for the second equivalence, Theorem 6.54 for the third equivalence and the last follows from the definition of *surjective*.

(b) We have:

$$\begin{aligned} T \text{ is surjective} &\iff \dim \text{range } T = \dim V \\ &\iff \dim (\text{range } T)^\perp = 0 \\ &\iff \dim \text{null } T^* = 0 \\ &\iff T^* \text{ is injective.} \end{aligned}$$

Here we used the same properties of range and null space as in (a), and a different identity from 7.6, relating null space of T^* with range of T . \square

7 Prove that if $T \in \mathcal{L}(V, W)$, then

$$(a) \dim \text{null } T^* = \dim \text{null } T + \dim W - \dim V;$$

$$(b) \dim \text{range } T^* = \dim \text{range } T$$

Solution:

(a) Using 7.6, 6.51 and Fundamental Theorem of Linear Maps, we get:

$$\begin{aligned} \dim \text{null } T^* &= \dim (\text{range } T)^\perp \\ &= \dim W - \dim \text{range } T = \dim W - (\dim V - \dim \text{null } T) \\ &= \dim \text{null } T + \dim W - \dim V. \quad \square \end{aligned}$$

(b) Here we can use result of part (a) to get:

$$\begin{aligned} \dim \text{range } T^* &= \dim W - \dim \text{null } T^* \\ &= \dim W - (\dim \text{null } T + \dim W - \dim V) \\ &= \dim V - \dim \text{null } T \\ &= \dim \text{range } T. \quad \square \end{aligned}$$

8 Suppose A is an m -by- n matrix with entries in \mathbb{F} . Use (b) in Exercise 7 to prove that the row rank of A equals the column rank of A .

Solution:

Suppose V, W are vector spaces over \mathbb{F} , $T \in \mathcal{L}(V, W)$ and A is a matrix of T with respect to some bases.

By Theorem 3.78, column rank of A equals $\dim \text{range } T$. According to the result of *Problem 7A.7b*, $\dim \text{range } T = \dim \text{range } T^*$, which in turn equals column rank of A^* , matrix of T^* , conjugate transpose of A .

Row rank of A equals column rank of A^t . Complex conjugation does not affect column (or row) rank, as span of columns does not change. If $\mathbb{F} = \mathbb{R}$, this is trivially true.

In case $\mathbb{F} = \mathbb{C}$, let k 'th entry of j 'th column of A^t equal $a_{k,j} = x_{k,j} + iy_{k,j}$. Suppose that rank of A^t equals m ; without loss of generality let the first m columns of A^t be linearly independent. Thus, for every c_1, \dots, c_m

$$\begin{aligned} c_1 a_{k,1} + \dots + c_m a_{k,m} &= c_1 (x_{k,1} + iy_{k,1}) + \dots + c_m (x_{k,1} + iy_{k,1}) \\ &= c_1 x_{k,1} + \dots + c_m x_{k,m} + i(c_1 y_{k,1} + \dots + c_m y_{k,m}) \\ &\neq 0. \end{aligned}$$

This implies that the sum of real or imaginary parts does not equal zero.

For columns of A^* we have entries $a_{k,j} = x_{k,j} - iy_{k,j}$. The sums are:

$$\begin{aligned} c_1 a_{k,1}^* + \cdots + c_m a_{k,m}^* &= c_1(x_{k,1} - iy_{k,1}) + \cdots + c_m(x_{k,1} - iy_{k,1}) \\ &= c_1 x_{k,1} + \cdots + c_m x_{k,m} - i(c_1 y_{k,1} + \cdots + c_m y_{k,m}) \\ &\neq 0. \end{aligned}$$

The last inequality follows from the fact that either the real or imaginary sum does not equal zero. Thus, span of columns of A^* is not less than span of columns of A^t .

Similarly, take a linearly dependent list of columns of A^t and take coefficients c_j that make a linear combination of the columns equal zero. Then, per-row sums of real and imaginary parts of entries of A^t equal zero. Under complex conjugation only the sign of imaginary part changes, therefore, per-row sum of entries of A^* also equals zero. This shows that column rank of A^* is not greater than the column rank of A^t .

Thus, we have: column rank of A equals column rank of A^* , which equals to column rank of A^t , which equals to row rank of A , proving the desired equality. \square

9 Prove that the product of two self-adjoint operators on V is self-adjoint if and only if the two operators commute.

Solution:

Suppose $T, S \in \mathcal{L}(V)$ are self-adjoint operators. Then we have:

$$TS = ST \iff TS = S^*T^* \iff TS = (TS)^*,$$

where we used definition of self-adjoint and property of the adjoint (7.5 d). \square

10 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Prove that T is self-adjoint if and only if

$$\langle Tv, v \rangle = \langle T^*v, v \rangle$$

for all $v \in V$.

Solution:

First suppose T is self-adjoint. That means $T = T^*$, which trivially leads to equality $\langle Tv, v \rangle = \langle T^*v, v \rangle$.

Now suppose $\langle Tv, v \rangle = \langle T^*v, v \rangle$. Using definition of adjoint, property (7.5 c) $(T^*)^* = T$ and conjugate symmetry of inner products, we get

$$\langle T^*v, v \rangle = \langle v, Tv \rangle = \overline{\langle Tv, v \rangle}.$$

Thus, we have $\langle Tv, v \rangle = \overline{\langle Tv, v \rangle}$, which implies that $\langle Tv, v \rangle \in \mathbb{R}$ for all $v \in V$. That by Theorem 7.14 implies that T is self-adjoint, completing the proof. \square

11 Define an operator $S : \mathbb{F}^2 \rightarrow \mathbb{F}^2$ by $S(w, z) = (-z, w)$.

- (a) Find a formula for S^* .
- (b) Show that S is normal but not self-adjoint.
- (c) Find all eigenvalues of S .

Solution:

(a) To find formula for S^* , suppose $(w, z), (x, y) \in \mathbb{F}^2$. Then:

$$\langle S(w, z), (x, y) \rangle = \langle (-z, w), (x, y) \rangle = -zx + wy = \langle (w, z), (y, -x) \rangle.$$

This implies $S^*(w, z) = (z, -w)$.

(b) Formula for S^* clearly shows that S is not self-adjoint.

$$\begin{aligned} SS^*(w, z) &= S(z, -w) = (w, z) \\ S^*S(w, z) &= S^*(-z, w) = (w, z). \end{aligned}$$

Last two equations show that $SS^* = S^*S$, meaning S is a normal operator.

(c) Suppose λ is an eigenvalue of S . Then:

$$\begin{cases} -z = \lambda w, \\ w = \lambda z. \end{cases}$$

Eliminating z in the second equation via expression in the first we get:

$$w = -\lambda^2 w \quad \Rightarrow \quad (\lambda^2 + 1)w = 0.$$

As we need a non-zero eigenvector, $w \neq 0$. Hence we have equation on eigenvalues:

$$\lambda^2 + 1 = 0.$$

If $\mathbb{F} = \mathbb{R}$, there are no eigenvalues. If $\mathbb{F} = \mathbb{C}$, $\lambda = \pm i$. \square

12 An operator $B \in \mathcal{L}(V)$ is called *skew* if

$$B^* = -B.$$

Suppose that $T \in \mathcal{L}(V)$. Prove that T is normal if and only if there exist commuting operators A and B such that A is self-adjoint, B is a skew operator, and $T = A + B$.

Solution:

First suppose T is normal. Let

$$A = \frac{T + T^*}{2} \quad \text{and} \quad B = \frac{T - T^*}{2}. \quad (7.1)$$

Then A is self-adjoint, B is a skew operator, and $T = A + B$. Commutator of A and B equals:

$$\begin{aligned} AB - BA &= \frac{(T + T^*)(T - T^*)}{2} - \frac{(T - T^*)(T + T^*)}{2} \\ &= \frac{T^2 - (T^*)^2 - TT^* + T^*T - T^2 + (T^*)^2 - TT^* + T^*T}{2} \\ &= T^*T - TT^*. \end{aligned} \quad (7.2)$$

Because T is normal, the right side of the equation above equals 0. Thus the operators A and B commute, as desired.

To prove the implication in the other direction, now suppose there exist commuting operators A and B such that A is self-adjoint, B is skew operator, and $T = A + B$. Then $T^* = A - B$. Adding the last two equations and then dividing by 2 produces the equation for A in 7.1. Subtracting the last two equations and then dividing by 2 produces the equation for B in 7.1. Now 7.1 implies 7.2. Because A and B commute, 7.2 implies that T is normal, as desired. \square

13 Suppose $\mathbb{F} = \mathbb{R}$. Define $\mathcal{A} \in \mathcal{L}(\mathcal{L}(V))$ by $\mathcal{A}T = T^*$ for all $T \in \mathcal{L}(V)$.

- (a) Find all eigenvalues of \mathcal{A} .
- (b) Find the minimal polynomial of \mathcal{A} .

Solution:

Using property 7.5 c of adjoint, we have:

$$\mathcal{A}^2 T = T \quad \Rightarrow \quad (\mathcal{A}^2 - \mathcal{I})T = 0.$$

Hence the minimal polynomial of \mathcal{A} is $p(z) = z^2 - 1$.

Eigenvalues of \mathcal{A} are roots of the minimal polynomial: ± 1 . \square

14 Define an inner product on $\mathcal{P}_2(\mathbb{R})$ by $\langle p, q \rangle = \int_0^1 pq$. Define an operator $T \in \mathcal{L}(\mathcal{P}_2(\mathbb{R}))$ by

$$T(ax^2 + bx + c) = bx.$$

- (a) Show that with this inner product, the operator T is not self-adjoint.
- (b) The matrix of T with respect to the basis $1, x, x^2$ is

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

This matrix equals its conjugate transpose, even though T is not self-adjoint. Explain why this is not a contradiction.

Solution:

If T were self-adjoint, we would have an equality $\langle Tp, q \rangle = \langle p, Tq \rangle$ for any $p, q \in \mathcal{P}_2(\mathbb{R})$.

Let $p = a_1x^2 + b_1x + c_1$ and $q = a_2x^2 + b_2x + c_2$ for some $a_1, a_2, b_1, b_2, c_1, c_2 \in \mathbb{R}$. Then we have:

$$\begin{aligned} \langle Tp, q \rangle &= \langle b_1x, a_2x^2 + b_2x + c_2 \rangle \\ &= b_1 \int_0^1 (a_2x^3 + b_2x^2 + c_2x) dx \\ &= b_1 \left(a_2 \frac{x^4}{4} + b_2 \frac{x^3}{3} + c_2 \frac{x^2}{2} \right) \Big|_0^1 \\ &= \frac{b_1a_2}{4} + \frac{b_1b_2}{3} + \frac{b_1c_2}{2} \end{aligned}$$

$$\begin{aligned} \langle p, Tq \rangle &= \langle a_1x^2 + b_1x + c_1, b_2x \rangle \\ &= b_2 \int_0^1 (a_1x^3 + b_1x^2 + c_1x) dx \\ &= b_2 \left(a_1 \frac{x^4}{4} + b_1 \frac{x^3}{3} + c_1 \frac{x^2}{2} \right) \Big|_0^1 \\ &= \frac{b_2a_1}{4} + \frac{b_1b_2}{3} + \frac{b_2c_1}{2} \end{aligned}$$

Therefore, $\langle Tp, q \rangle \neq \langle p, Tq \rangle$ for all p, q , thus T is not self-adjoint. \square

(b) Basis $1, x, x^2$ is *not orthonormal*, while Theorem 7.9 states that matrix of T^* equals complex conjugate transpose of the matrix of T when evaluated in an *orthonormal basis*. Thus, there is no contradiction.

15 Suppose $T \in \mathcal{L}(V)$ is invertible. Prove that

- (a) T is self-adjoint $\iff T^{-1}$ is self-adjoint;

(b) T is normal $\iff T^{-1}$ is normal.

Solution:

(a) Suppose T is self-adjoint. Then by property 7.5 f, we have

$$(T^{-1})^* = (T^*)^{-1} = T^{-1},$$

thus, T^{-1} is self-adjoint.

Changing T to T^{-1} and using property $(T^{-1})^{-1} = T$ (see *Problem 3D.1*), we get the proof in other direction.

(b) Suppose T is normal. Then we have

$$\begin{aligned} T^{-1}(T^{-1})^* &= T^{-1}(T^*)^{-1} = (T^*T)^{-1} \\ &= (TT^*)^{-1} \\ &= (T^*)^{-1}T^{-1} \\ &= (T^{-1})^*T^{-1}, \end{aligned}$$

where we use property of inverse $((TS)^{-1} = S^{-1}T^{-1}$, see *Problem 3D.2*), property of adjoint 7.5 f and normality of T . This shows that T^{-1} is also normal.

Changing T to T^{-1} and using $(T^{-1})^{-1} = T$, we get the proof in other direction. \square

16 Suppose $\mathbb{F} = \mathbb{R}$.

- (a) Show that the set of self-adjoint operators on V is a subspace of $\mathcal{L}(V)$.
(b) What is the dimension of the subspace of $\mathcal{L}(V)$ in (a) [in terms of $\dim V$]?

Solution:

(a) We need to check three conditions of Theorem 1.34.

- 0 is a self-adjoint operator. \checkmark
- Suppose S and T are self-adjoint. Then $(S + T)^* = S^* + T^* = S + T$, hence self-adjoint operators are closed under addition. \checkmark
- Suppose T is self-adjoint and $\alpha \in \mathbb{R}$. Then $(\alpha T)^* = \overline{\alpha}T^* = \alpha T$, hence self-adjoint operators are closed under scalar multiplication. \checkmark

Thus, the set of self-adjoint operators on V is a subspace of $\mathcal{L}(V)$. \square

(b) Let e_1, \dots, e_n be an orthonormal basis of V . In this basis, symmetric matrices represent self-adjoint operators on V . Every symmetric matrix can

be constructed from a matrix with either only one non-zero entry on the diagonal or two equal non-zero entries ($A_{j,k}$ and $A_{k,j}$). Therefore, dimension of the subspace of self-adjoint operators equals:

$$n + \frac{n^2 - n}{2} = \frac{n^2 + n}{2} = \dim V(\dim V + 1)/2$$

17 Suppose $\mathbb{F} = \mathbb{C}$. Show that the set of self-adjoint operators on V is not a subspace of $\mathcal{L}(V)$.

Solution:

On the complex vector spaces, the set of self-adjoint operators is not closed under scalar multiplication:

$$(\alpha T)^* = \bar{\alpha} T^* = \bar{\alpha} T.$$

If α has an imaginary part, $\bar{\alpha} \neq \alpha$, hence $(\alpha T)^* \neq \alpha T$. \square

18 Suppose $\dim V \geq 2$. Show that the set of normal operators on V is not a subspace of $\mathcal{L}(V)$.

Solution:

Suppose $S, T \in \mathcal{L}(V)$ are normal operators that do not commute and $ST^* - T^*S$ has a real component. Then their sum is not a normal operator:

$$\begin{aligned} (S + T)(S + T)^* - (S + T)^*(S + T) &= SS^* + TT^* + ST^* + TS^* \\ &\quad - S^*S - T^*T - S^*T - T^*S \\ &= (ST^* - T^*S) + (TS^* - S^*T) \\ &= (ST^* - T^*S) + (ST^* - T^*S)^* \\ &= 2\Re(ST^* - T^*S) \\ &\neq 0 \end{aligned}$$

19 Suppose $T \in \mathcal{L}(V)$ and $\|T^*v\| \leq \|Tv\|$ for every $v \in V$. Prove that T is normal.

Solution:

Suppose e_1, \dots, e_n is an orthonormal basis of V . Then (by *Problem 7A.5*) we have:

$$\|Te_1\|^2 + \dots + \|Te_n\|^2 = \|T^*e_1\|^2 + \dots + \|T^*e_n\|^2. \quad (7.3)$$

This, together with $\|T^*v\| \leq \|Tv\|$, implies that $\|Te_j\|^2 = \|T^*e_j\|^2$ for every e_j in the basis. Indeed, we can rearrange terms in [7.3](#) as:

$$\|Te_1\|^2 - \|T^*e_1\|^2 = (\|T^*e_2\|^2 - \|Te_2\|^2) + \dots + (\|T^*e_n\|^2 - \|Te_n\|^2). \quad (7.4)$$

The left-hand side of 7.4 is greater than or equal to zero, meanwhile the right-hand side is less than or equal to zero (as every term on the right side is less than or equal to zero). Therefore, $\|Te_1\| = \|T^*e_1\|$. Similarly, this equality can be shown for any other e_j .

Let $v = \alpha e_1$, then

$$\|Tv\| = \|T(\alpha e_1)\| = |\alpha|\|Te_1\| = |\alpha|\|T^*e_1\| = \|T^*(\alpha e_1)\| = \|T^*v\|.$$

Since the orthonormal basis is arbitrary, we can construct one starting from any arbitrary $v \in V$ using the Gram-Schmidt procedure (6.32). This implies $\|Tv\| = \|T^*v\|$ for every $v \in V$, hence T is normal (Theorem 7.20). \square

20 Suppose $P \in \mathcal{L}(V)$ is such that $P^2 = P$. Prove that the following are equivalent.

- (a) P is self-adjoint.
- (b) P is normal.
- (c) There is a subspace U of V such that $P = P_U$.

Solution:

First suppose P is self-adjoint. Then it automatically means P is normal.

Now suppose P is normal. Then, $\text{range } P = \text{range } P^*$ (Theorem 7.21) and $\text{null } P = (\text{range } P^*)^\perp$ (Theorem 7.6), which implies $\text{null } P = (\text{range } P)^\perp$. Thus, we have that every vector in the null space of P is orthogonal to every vector in range of P and $P = P^2$, which implies (by *Problem 6C.9*) that there exists a subspace U of V such that $P = P_U$.

Finally, suppose P is an orthogonal projection on some subspace U of V . Let $u_1, u_2 \in U$ and $w_1, w_2 \in U^\perp$. We have

$$\begin{aligned}\langle P(u_1 + w_1), u_2 + w_2 \rangle &= \langle u_1, u_2 + w_2 \rangle = \langle u_1, u_2 \rangle \\ \langle P(u_1 + w_1), u_2 + w_2 \rangle &= \langle u_1 + w_1, P^*(u_2 + w_2) \rangle.\end{aligned}$$

Two equations above imply that $P^*(u_2 + w_2) = u_2$ for any $u_2 \in U$ and $w_2 \in U^\perp$. This coincides with the definition of orthogonal projection on U , therefore $P = P^*$, hence P is self-adjoint.

Thus, we have shown that (a) implies (b), (b) implies (c) and (c) implies (a), hence these three statements are equivalent. \square

21 Suppose $D : \mathcal{P}_8(\mathbb{R}) \rightarrow \mathcal{P}_8(\mathbb{R})$ is the differentiation operator defined by $Dp = p'$. Prove that there does not exist an inner product on $\mathcal{P}_8(\mathbb{R})$ that makes D a normal operator.

Solution:

Suppose there is an inner product such that D is a normal operator.

By Theorem 7.21, $\text{range } D^* = \text{range } D$.

Now note that for any $p \in \mathcal{P}_8(\mathbb{R})$:

$$\begin{aligned}\langle Da_0, p \rangle &= \langle 0, p \rangle = 0 \\ \langle Da_0, p \rangle &= \langle a_0, D^*p \rangle\end{aligned}$$

where a_0 is a constant polynomial. This equation implies that $D^*p \in (\text{span}(1))^\perp$. Thus, $\text{range } D \subset (\text{span}(1))^\perp$.

At the same time, $Dx = 1 \in \text{range } D$ and $1 \notin (\text{span}(1))^\perp$. Hence, our assumption leads to a contradiction, and there is no inner product such that D is a normal operator. \square

Comment: This problem can be extended to any finite-dimensional polynomial vector space with dimension greater than 1, as only this fact is used in the proof.

22 Give an example of an operator $T \in \mathcal{L}(\mathbb{R}^3)$ such that T is normal but not self-adjoint.

Solution:

Let T be an operator on \mathbb{R}^3 , with matrix in standard basis:

$$\mathcal{M}(T) = \begin{pmatrix} 1 & 1 & 0 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{pmatrix}.$$

Then, the matrix of adjoint operator T^* is:

$$\mathcal{M}(T^*) = \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & -1 \\ 0 & 1 & 1 \end{pmatrix}.$$

T is clearly not self-adjoint. Yet it is normal, as can be checked by matrix multiplication:

$$\begin{aligned}\begin{pmatrix} 1 & 1 & 0 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & -1 \\ 0 & 1 & 1 \end{pmatrix} &= \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & -1 \\ 0 & 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 1 & 0 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 2 & 0 & -1 \\ 0 & 3 & 0 \\ -1 & 0 & 2 \end{pmatrix}.\end{aligned}$$

23 Suppose T is a normal operator on V . Suppose also that $v, w \in V$ satisfy the equations

$$\|v\| = \|w\| = 2, \quad Tv = 3v, \quad Tw = 4w.$$

Show that $\|T(v + w)\| = 10$.

Solution:

Here we use Theorem 7.22. Vectors v and w are eigenvectors of T , corresponding to distinct eigenvalues, hence they are orthogonal. Then we use Pythagorean theorem (6.12) to compute the norm directly:

$$\begin{aligned} \|T(v + w)\| &= \|3v + 4w\| = \sqrt{\|3v\|^2 + \|4w\|^2} \\ &= \sqrt{9\|v\|^2 + 16\|w\|^2} \\ &= \sqrt{9 \cdot 4 + 16 \cdot 4} \\ &= 10. \quad \square \end{aligned}$$

24 Suppose $T \in \mathcal{L}(V)$ and

$$a_0 + a_1z + a_2z^2 + \cdots + a_{m-1}z^{m-1} + z^m$$

is the minimal polynomial of T . Prove that the minimal polynomial of T^* is

$$\overline{a_0} + \overline{a_1}z + \overline{a_2}z^2 + \cdots + \overline{a_{m-1}}z^{m-1} + z^m$$

Solution:

First, note that every $v, u \in V$:

$$\langle p(T)v, u \rangle = 0 = \langle v, (p(T))^*u \rangle \quad (7.5)$$

hence $(p(T))^* = 0$. Expanding adjoint of $p(T)$ we get:

$$\begin{aligned} (p(T))^* &= (a_0I)^* + (a_1T)^* + (a_2T^2)^* + \cdots + (a_mT^{m-1})^* + (T^m)^* \\ &= \overline{a_0}I + \overline{a_1}T^* + \overline{a_2}(T^*)^2 + \cdots + \overline{a_m}(T^*)^{m-1} + (T^*)^m. \end{aligned}$$

Now suppose that there is a polynomial $q(z) \neq (\overline{a_0} + \overline{a_1}z + \cdots + z^m)$ such that $q(T^*) = 0$ and $\deg q \leq \deg p$. Reversing 7.5 with $q(z)$ in place of $p(z)$ we conclude that $q(T) = 0$ (that is, $q(T)$ with all coefficients turned into their complex conjugate). That would imply that $p(z)$ is not a minimal polynomial of T , being either of not the least degree or not unique. Hence, we must conclude that

$$\overline{a_0} + \overline{a_1}z + \overline{a_2}z^2 + \cdots + \overline{a_{m-1}}z^{m-1} + z^m$$

is a minimal polynomial of T^* . \square

25 Suppose $T \in \mathcal{L}(V)$. Prove that T is diagonalizable if and only if T^* is diagonalizable.

Solution:

By Theorem 5.62, T is diagonalizable if and only if the minimal polynomial of T equals $(z - \lambda_1) \dots (z - \lambda_m)$ for some list of distinct $\lambda_1, \dots, \lambda_m \in \mathbb{F}$. Following argument of the previous problem, we see that the minimal polynomial of T^* is $q(z)$ such that $q(T^*) = (p(T))^*$. Thus, we have:

$$\begin{aligned} q(T^*) &= [(T - \lambda_1 I) \dots (T - \lambda_m I)]^* = \\ &= (T - \lambda_m)^* \dots (T - \lambda_1 I)^* \\ &= (T^* - \overline{\lambda_m} I) \dots (T^* - \overline{\lambda_1} I). \end{aligned}$$

As $\lambda_1, \dots, \lambda_m$ are distinct, so are $\overline{\lambda_m}, \dots, \overline{\lambda_1}$. Thus, the minimal polynomial of T^* has the desired form of a product of distinct $(z - \alpha_i)$ terms, which implies that T^* is diagonalizable.

Reversing proof with T^* in place of T , gives implication in other direction.

□

26 Fix $u, x \in V$. Define $T \in \mathcal{L}(V)$ by $Tv = \langle v, u \rangle x$ for every $v \in V$.

- (a) Prove that if V is a real vector space, then T is self-adjoint if and only if the list u, x is linearly dependent.
- (b) Prove that T is normal if and only if the list u, x is linearly dependent.

Solution:

(a) First, suppose that T is self-adjoint. Let v, w be arbitrary vectors in V . Then the inner product of Tv and w is:

$$\langle Tv, w \rangle = \langle \langle v, u \rangle x, w \rangle = \langle v, u \rangle \langle x, w \rangle,$$

and also:

$$\langle Tv, w \rangle = \langle v, Tw \rangle = \langle v, \langle w, u \rangle x \rangle = \langle v, x \rangle \langle w, u \rangle.$$

Thus we have:

$$\begin{aligned} \langle v, u \rangle \langle x, w \rangle - \langle v, x \rangle \langle w, u \rangle &= 0 \\ \langle v, \langle x, w \rangle u - \langle w, u \rangle x \rangle &= 0 \end{aligned}$$

for every $v, w \in V$. This implies that $\langle x, w \rangle u - \langle w, u \rangle x = 0$, hence u, x is a linearly dependent list.

Now to proof the other direction, suppose u, x is a linearly dependent list. Then $u = \lambda x$, where $\lambda \in \mathbb{R}$. Let $v, w \in V$, then we have:

$$\begin{aligned}\langle Tv, w \rangle &= \langle \langle v, u \rangle x, w \rangle = \langle \langle v, \lambda x \rangle x, w \rangle \\ &= \lambda \langle v, x \rangle \langle x, w \rangle = \lambda \langle v, x \rangle \langle w, x \rangle \\ &= \langle v, \langle w, \lambda x \rangle x \rangle \\ &= \langle v, \langle w, u \rangle x \rangle \\ &= \langle v, T^* w \rangle.\end{aligned}$$

This implies that $T^* = T$, i.e. T is self-adjoint. \square

(b) Before the proof itself, we must explicitly find T^* for this case. Following the previous part, we have for $v, w \in V$:

$$\langle Tv, w \rangle = \langle v, u \rangle \langle x, w \rangle = \langle v, \langle w, x \rangle u \rangle.$$

Thus, $T^*v = \langle v, x \rangle u$.

Now, we suppose that T is normal. Then

$$TT^*v = T(\langle v, x \rangle u) = \langle \langle v, x \rangle u, u \rangle x = \langle v, x \rangle \|u\|^2 x,$$

and

$$T^*Tv = T^*(\langle v, u \rangle x) = \langle \langle v, u \rangle x, x \rangle u = \langle v, u \rangle \|x\|^2 u.$$

For a normal operator we have $TT^* - T^*T = 0$, hence

$$\langle v, x \rangle \|u\|^2 x = \langle v, u \rangle \|x\|^2 u$$

for every $v \in V$. Thus, the list u, x is linearly dependent.

For a proof in other direction, suppose that $u = \lambda x$, where $\lambda \in \mathbb{C}$. We have

$$\begin{aligned}\|Tv\| &= \|\langle v, u \rangle x\| = \|\langle v, \lambda x \rangle x\| \\ &= \|\bar{\lambda} \langle v, x \rangle x\| = |\lambda| \cdot \|\langle v, x \rangle x\| \\ &= \|\lambda \langle v, x \rangle x\| = \|\langle v, x \rangle u\| \\ &= \|T^*v\|.\end{aligned}$$

Thus, by Theorem 7.20, T is normal, completing the proof. \square

27 Suppose $T \in \mathcal{L}(V)$ is normal. Prove that

$$\text{null } T^k = \text{null } T \quad \text{and} \quad \text{range } T^k = \text{range } T$$

for every positive integer k .

Solution:

Firstly, for $k = 1$, the theorem is obviously true, so we will assume $k \geq 2$ in the rest of the proof.

That $\text{null } T \subseteq \text{null } T^k$ and $\text{range } T \subseteq \text{range } T^k$ (for any operator), is true, as can be easily seen. We will prove the other direction of inclusion.

First, for a self-adjoint operator S (here it will be T^*T), suppose that $v \in \text{null } S^k$. Then we have:

$$0 = \langle S^k v, S^{k-2} v \rangle = \langle S^{k-1} v, S^{k-1} v \rangle.$$

Thus, $\|S^{k-1} v\| = 0$, which implies $S^{k-1} v = 0$, therefore $\text{null } S^k \subseteq \text{null } S^{k-1}$. Repeating the induction on k until $k - 1 = 1$, we have that for every positive integer k , $\text{null } S^k \subseteq \text{null } S$. Hence, $\text{null } S^k = \text{null } S$.

Now we examine a normal operator T . Suppose $v \in \text{null } T^k$ for some positive integer k . Then.

$$T^k v = 0 \Rightarrow (T^*)^k T^k v = 0 \Rightarrow (T^* T)^k v = 0,$$

where the second implication is valid because T and T^* commute. Thus, $v \in \text{null } (T^* T)^k$, which implies $v \in \text{null } T^* T$. Hence

$$0 = \langle T^* T v, v \rangle = \langle T v, T v \rangle \iff T v = 0 \iff v \in \text{null } T.$$

Thus, we have shown $\text{null } T^k = \text{null } T$ for every positive integer k .

Finally, using that T^k is also a normal operator, we see that

$$\text{range } T^k = (\text{null } (T^k)^*)^\perp = (\text{null } T^k)^\perp = (\text{null } T)^\perp = \text{range } T^* = \text{range } T,$$

completing the proof. \square

28 Suppose $T \in \mathcal{L}(V)$ is normal. Prove that if $\lambda \in \mathbb{F}$, then the minimal polynomial of T is not a polynomial multiple of $(x - \lambda)^2$.

Solution:

Let $p(z)$ be a minimal polynomial of T and suppose that it is a polynomial multiple of $(z - \lambda)^2$:

$$p(z) = (z - \lambda)^2 q(z)$$

for some polynomial $q(z)$.

Then we have for every $v \in V$:

$$(T - \lambda I)^2 q(T) v = 0 \Rightarrow q(T) v \in \text{null } (T - \lambda I)^2.$$

By property of normal operator 7.21 (d), $(T - \lambda I)$ is a normal operator. Result of the previous problem thus implies that $q(T)v \in \text{null}(T - \lambda I)$. Thus for every $v \in V$:

$$(T - \lambda I)q(T)v = 0.$$

But this polynomial has a degree less than $p(z)$, contradicting the fact that $p(z)$ is a minimal polynomial of T . Hence, $p(z)$ cannot be a polynomial multiple of $(z - \lambda)^2$ for any $\lambda \in \mathbb{F}$. \square

29 Prove or give a counterexample: If $T \in \mathcal{L}(V)$ and there is an orthonormal basis e_1, \dots, e_n of V such that $\|Te_k\| = \|T^*e_k\|$ for each $k = 1, \dots, n$, then T is normal.

Solution:

Let $\mathbb{F} = \mathbb{R}$ and take the operator T and its adjoint, defined by matrices, with respect to the standard basis:

$$\mathcal{M}(T) = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 2 & 0 \\ 0 & 1 & 3 \end{pmatrix} \quad \mathcal{M}(T^*) = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 2 & 1 \\ 1 & 0 & 3 \end{pmatrix}$$

As can be checked with matrix multiplication, these operators do not commute:

$$\begin{aligned} \mathcal{M}(T) \cdot \mathcal{M}(T^*) &= \begin{pmatrix} 2 & 1 & 3 \\ 1 & 5 & 2 \\ 3 & 2 & 10 \end{pmatrix} \\ \mathcal{M}(T^*) \cdot \mathcal{M}(T) &= \begin{pmatrix} 2 & 2 & 1 \\ 2 & 5 & 3 \\ 1 & 3 & 10 \end{pmatrix}. \end{aligned}$$

Hence, T is not a normal operator. Meanwhile, for vectors of the basis we have:

$$\begin{aligned} Te_1 &= e_1 + e_2, & T^*e_1 &= e_1 + e_3, \\ Te_2 &= 2e_2 + e_3, & T^*e_2 &= e_1 + 2e_2, \\ Te_3 &= e_1 + 3e_3, & T^*e_3 &= e_2 + 3e_3. \end{aligned}$$

So we have $\|Te_k\| = \|T^*e_k\|$ for every $k = 1, 2, 3$, but T is not normal, counterproving the statement of the problem. \square

30 Suppose that $T \in \mathcal{L}(\mathbb{F}^3)$ is normal and $T(1, 1, 1) = (2, 2, 2)$. Suppose $(z_1, z_2, z_3) \in \text{null } T$. Prove that $z_1 + z_2 + z_3 = 0$.

Solution:

Vector $(1, 1, 1)$ is an eigenvector of T with eigenvalue 2; (z_1, z_2, z_3) is an eigenvector of T with eigenvalue 0. By Theorem 7.22, these two vectors are orthogonal. Hence

$$0 = \langle (z_1, z_2, z_3), (1, 1, 1) \rangle = z_1 + z_2 + z_3,$$

as desired. \square

31 Fix a positive integer n . In the inner product space of continuous real-valued functions on $[-\pi, \pi]$ with inner product $\langle f, g \rangle = \int_{-\pi}^{\pi} fg$, let

$$V = \text{span}(1, \cos x, \cos 2x, \dots, \cos nx, \sin x, \sin 2x, \dots, \sin nx).$$

- (a) Define $D \in \mathcal{L}(V)$ by $Df = f'$. Show that $D^* = -D$. Conclude that D is normal but not self-adjoint.
- (b) Define $T \in \mathcal{L}(V)$ by $Tf = f''$. Show that T is self-adjoint.

Solution:

(a) Earlier (in *Problem 6B.4*) we have shown that

$$\frac{1}{\sqrt{2\pi}}, \frac{\cos x}{\sqrt{\pi}}, \frac{\cos 2x}{\sqrt{\pi}}, \dots, \frac{\cos nx}{\sqrt{\pi}}, \frac{\sin x}{\sqrt{\pi}}, \frac{\sin 2x}{\sqrt{\pi}}, \dots, \frac{\sin nx}{\sqrt{\pi}}$$

is an orthonormal list. Hence, this list is an orthonormal basis of V . Operator D acts on the basis vectors as follows

$$\begin{aligned} D\left(\frac{1}{\sqrt{2\pi}}\right) &= 0 \\ D\left(\frac{\cos kx}{\sqrt{\pi}}\right) &= -k \frac{\sin kx}{\sqrt{\pi}} \\ D\left(\frac{\sin kx}{\sqrt{\pi}}\right) &= k \frac{\cos kx}{\sqrt{\pi}}. \end{aligned}$$

Thus, in this basis, the matrix of D is

$$\mathcal{M}(D) = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & n \\ 0 & -1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & -2 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & -n & 0 & 0 & \cdots & 0 \end{pmatrix}$$

Matrix of D^* is a transpose of this matrix. We see that $(\mathcal{M}(D))^t = -\mathcal{M}(D)$, hence $D^* = -D$.

Clearly, D is not self-adjoint, but it is indeed normal:

$$DD^* = D(-D) = -D^2 = (-D)D = D^*D. \quad \square$$

(b) Working in the same basis, we have:

$$\begin{aligned} T\left(\frac{1}{\sqrt{2\pi}}\right) &= 0 \\ T\left(\frac{\cos kx}{\sqrt{\pi}}\right) &= -k^2 \frac{\cos kx}{\sqrt{\pi}} \\ T\left(\frac{\sin kx}{\sqrt{\pi}}\right) &= -k^2 \frac{\sin kx}{\sqrt{\pi}}. \end{aligned}$$

Thus, the matrix of T is

$$\mathcal{M}(T) = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & -1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & -4 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & -n^2 \\ 0 & -1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & -4 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & -n^2 & 0 & 0 & \cdots & 0 \end{pmatrix}.$$

This matrix is symmetric and hence T is a self-adjoint operator. \square

32 Suppose $T : V \rightarrow W$ is a linear map. Show that under the standard identification of V with V' and the corresponding identification of W with W' , the adjoint map $T^* : W \rightarrow V$ corresponds to the dual map $T' : W' \rightarrow V'$. More precisely, show that

$$T'(\varphi_w) = \varphi_{T^*w}$$

for all $w \in W$, where φ_w and φ_{T^*w} are defined as in 6.58.

Solution:

Following Riesz representation theorem, we define $\varphi_v(u)$ as

$$\varphi_v(u) = \langle u, v \rangle,$$

where v, u are either in V , or in W , and we use the inner product defined on the corresponding vector space.

Let $v \in V$, $w \in W$. Then, using definition of dual map and adjoint, we have:

$$\begin{aligned} (T'(\varphi_w))(v) &= (\varphi_w \circ T)v = \varphi_w(Tv) \\ &= \langle Tv, w \rangle = \langle v, T^*w \rangle \\ &= \varphi_{T^*w}(v), \end{aligned}$$

as desired. \square

7B Spectral Theorem

1 Prove that a normal operator on a complex inner product space is self-adjoint if and only if all its eigenvalues are real.

Solution:

Let $T \in \mathcal{L}(V)$ be a normal operator. This means T is diagonalizable in some orthonormal basis. Denote entries on the diagonal of T as $a_j + ib_j$; then entries on the diagonal of T^* are $a_j - ib_j$ (see Theorem 7.9).

Then note that T is self-adjoint if and only if $T = T^*$. This, in turn is equivalent to:

$$a_j + ib_j = a_j - ib_j \iff b_j = 0,$$

for all $j = 1, \dots, \dim V$, thus, eigenvalues of T are purely real. \square

2 Suppose $\mathbb{F} = \mathbb{C}$. Suppose $T \in \mathcal{L}(V)$ is normal and has only one eigenvalue. Prove that T is a scalar multiple of the identity operator.

Solution:

T is normal, hence by Spectral Theorem it is diagonalizable. By Theorem 5.41, entries on the diagonal of T are precisely the eigenvalues of T . T has only one eigenvalue, hence all diagonal entries are equal (say, $\alpha \in \mathbb{C}$). Thus, matrix of T is a scalar multiple of the matrix of the identity operator, and hence, by linear map lemma (3.4), T is a scalar multiple of I . \square

3 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is normal. Prove the set of eigenvalues of T is contained in $\{0, 1\}$ if and only if there is a subspace U of V such that $T = P_U$.

Solution:

First suppose that there is a subspace U of V such that $T = P_U$. Let u_1, \dots, u_m be an orthonormal basis of U and w_1, \dots, w_n be an orthonormal basis of U^\perp . The combined list $u_1, \dots, u_m, w_1, \dots, w_n$ gives an orthonormal basis of V , because V is a direct sum of U and U^\perp (Theorem 6.49) and every vector in U is orthogonal to every vector in U^\perp by definition.

Note that $Tu_i = P_U u_i = u_i$ and $Tw_j = P_U w_j = 0$. Hence, u_i 's are eigenvectors of T with eigenvalue 1, and w_j 's are eigenvectors of T with eigenvalue 0. These are the maximum number of (linearly independent) eigenvectors, hence the set of all eigenvalues of T is $\{0, 1\}$.

Now suppose that the set of eigenvalues of T is contained in $\{0, 1\}$. T is normal, hence it is diagonalizable in some orthonormal basis, where basis vectors are eigenvectors of T . Let u_i 's be vectors of the basis, corresponding to the eigenvalue 1, and w_i 's be vectors of the basis, corresponding to the eigenvalue 0. Let $U = \text{span}(u_1, \dots, u_m)$ and $W = \text{span}(w_1, \dots, w_m)$. Note that $V = U \oplus W$, so that any $v \in V$ can be represented as $v = u + w$. Thus, we have:

$$Tv = T(u + w) = u.$$

Hence, T is the orthogonal projection on U , by definition, which completes the proof in other direction. \square

4 Prove that a normal operator on a complex inner product space is skew (meaning it equals the negative of its adjoint) if and only if all its eigenvalues are purely imaginary (meaning that they have real part equal to 0).

Solution:

Like in *Problem 7B.1*, we have entries on the diagonal of T equal $a_j + ib_j$ and entries on the diagonal of T^* equal $a_j - ib_j$.

T is skew if and only if $T = -T^*$. This is equivalent to:

$$a_j + ib_j = -a_j + ib_j \iff a_j = 0,$$

for all $j = 1, \dots, \dim V$, thus, eigenvalues of T are purely imaginary. \square

5 Prove or give a counterexample: If $T \in \mathcal{L}(\mathbb{C}^3)$ is a diagonalizable operator, then T is normal (with respect to the usual inner product).

Solution:

Take basis $(1, 0, 0), (1, 1, 0), (1, 1, 1)$; denote these vectors v_1, v_2, v_3 , accordingly. Let T be a diagonalizable operator on this basis, acting on the basis as follows:

$$Tv_1 = 2v_1, \quad Tv_2 = 3v_2, \quad Tv_3 = v_3.$$

A vector $v = (x, y, z) \in \mathbb{C}^3$ can be represented as a linear combination of basis vectors as follows:

$$v = (x - y)v_1 + (y - z)v_2 + zv_3.$$

Hence, T acting on v is

$$Tv = 2(x - y)v_1 + 3(y - z)v_2 + zv_3 = (2x + y - 2z, 3y - 2z, z).$$

Now we find the adjoint T^* . Let $u = (a, b, c)$:

$$\begin{aligned} \langle Tv, u \rangle &= \langle (2x + y - 2z, 3y - 2z, z), (a, b, c) \rangle \\ &= 2ax + ay - 2az + 3by - 2bz + cz \\ &= 2ax + (a + 3b)y + (c - 2a - 2b)z \\ &= \langle (x, y, z), (2a, a + 3b, -2a - 2b + c) \rangle \\ &= \langle v, T^*u \rangle \end{aligned}$$

Therefore,

$$T^*(x, y, z) = (2x, x + 3b, -2x - 2y + z).$$

Now we calculate norms of Tv and T^*v .

$$\begin{aligned} \|Tv\| &= \sqrt{4x^2 + 4xy - 8xz + 10y^2 - 16yz + 9z^2}, \\ \|T^*v\| &= \sqrt{9x^2 + 14xy - 4xz + 13y^2 - 4yz + z^2}, \end{aligned}$$

hence $\|Tv\|$ does not equal $\|T^*v\|$ for every $v \in V$, thus T is not normal (Theorem 7.20). \square

6 Suppose V is a complex inner product space and $T \in \mathcal{L}(V)$ is a normal operator such that $T^9 = T^8$. Prove that T is self-adjoint and $T^2 = T$.

Solution: Rearranging terms in $T^9 = T^8$ we get:

$$T^8(T - I) = 0.$$

By Theorem 5.29, $p(z) = z^8(z - 1)$ is a polynomial multiple of the minimal polynomial of T . This implies that eigenvalues of T are contained in set $\{0, 1\}$. Using *Problem 7B.3*, we have that there exists subspace $U \subseteq V$ such that $T = P_U$.

By properties of orthogonal projection (6.57), $P_U^2 = P_U$, and by *Problem 7A.20*, P_U is self-adjoint, which completes the proof. \square

7 Give an example of an operator T on a complex vector space such that $T^9 = T^8$ but $T^2 \neq T$.

Solution:

Let $T \in \mathcal{L}(\mathbb{C}^3)$ be an operator with the following matrix with respect to the standard basis:

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

As can be checked with matrix multiplication, matrix of T^2 is

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

hence, $T \neq T^2$. But we also have $T^8 = T^9 = 0$. \square

8 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Prove that T is normal if and only if every eigenvector of T is also an eigenvector of T^* .

Solution:

First, suppose T is normal. Then by Spectral Theorem, V has an orthonormal basis consisting of eigenvectors of T . Matrix of T is diagonal with respect to this basis. By Theorem 7.9, matrix of T^* with respect to the same basis is a conjugate transpose of the matrix of T , hence T^* is diagonalizable with respect to the chosen basis. By Theorem 5.55, those basis vectors are eigenvectors of T^* . Hence every eigenvector of T is an eigenvector of T^* ; other linearly independent eigenvectors cannot exist, as every list greater than basis is linearly dependent.

Now suppose that every eigenvector of T is an eigenvector of T^* . Let e_1, \dots, e_n be an orthonormal basis of V with respect to which T has an upper-triangular matrix (see Theorems 5.47 and 6.37). Matrix of T^* with respect to the same basis is lower triangular.

The vector e_1 is an eigenvector of T , hence it is also an eigenvector of T^* , which means that every entry in the first column of the matrix of T^* except the first equals zero. This implies that every entry in the first row of the matrix of T except first equals zero. This, in turn, means e_2 is now an eigenvector of T . Continuing this for all rows of the matrix of T , we get that T and T^* are actually diagonalizable with respect to the chosen basis, hence they commute (Theorem 5.76), meaning T is normal. \square

9 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Prove that T is normal if and only if there exists a polynomial $p \in \mathcal{P}(\mathbb{C})$ such that $T^* = p(T)$.

Solution:

First suppose that there exists a polynomial $p \in \mathcal{P}(\mathbb{C})$ such that $T^* = p(T)$. Then T commutes with T^* :

$$TT^* = Tp(T) = p(T)T = T^*T,$$

hence T is normal.

Now suppose that T is normal. With help of Spectral Theorem, we choose an orthonormal basis of V consisting of eigenvectors of T : v_1, \dots, v_m with corresponding eigenvalues $\lambda_1, \dots, \lambda_m$. The adjoint T^* is defined by its effect on this basis:

$$T^*v_i = \overline{\lambda_i}v_i, \quad \text{see Problem 7A.3.}$$

Let a polynomial $p(z) \in \mathcal{P}(\mathbb{C})$ be such that:

$$p(\lambda_i) = \overline{\lambda_i},$$

for every eigenvalue λ_i of T (such polynomial can be constructed, for example, by Lagrange polynomial method). Then for every v_i of the basis we have:

$$\begin{aligned} p(T)v_i &= (a_0I + a_1T + \dots + a_nT^n)v_i \\ &= (a_0 + \lambda_i + \dots \lambda_i^n)v_i \\ &= p(\lambda_i)v_i \\ &= \overline{\lambda_i}v_i. \end{aligned}$$

This equation implies that $T^* = p(T)$, as desired. \square

10 Suppose V is a complex inner product space. Prove that every normal operator on V has a square root.

Solution:

Every normal operator on a complex inner product space is diagonalizable (Spectral Theorem). Hence, if e_1, \dots, e_n is a basis of V , with respect to which normal $T \in \mathcal{L}(V)$ is diagonal, we have:

$$Te_i = \alpha_i e_i,$$

where $\alpha_i \in \mathbb{C}$. Define an operator $S \in \mathcal{L}(V)$ as follows:

$$Se_i = \sqrt{\alpha_i} e_i.$$

The square root is well-defined for every complex number, thus S exists indeed. Now it is easy to verify that $S^2 = T$, either with matrix multiplication, or:

$$S^2 e_i = S(Se_i) = S(\sqrt{\alpha_i} e_i) = \sqrt{\alpha_i} \cdot \sqrt{\alpha_i} e_i = \alpha_i e_i.$$

Thus, every normal operator on a complex inner product space has a square root. \square

11 Prove that every self-adjoint operator on V has a cube root.

Solution:

Every self-adjoint operator on a real inner product space is diagonalizable (Spectral Theorem). Hence, if e_1, \dots, e_n is a basis of V , with respect to which normal $T \in \mathcal{L}(V)$ is diagonal, we have:

$$Te_i = \alpha_i e_i,$$

where $\alpha_i \in \mathbb{C}$. Define an operator $S \in \mathcal{L}(V)$ as follows:

$$Se_i = \alpha_i^{1/3} e_i.$$

The cube root is well-defined for every real number, thus S exists indeed. Now it is easy to verify that $S^3 = T$, either with matrix multiplication, or:

$$S^3 e_i = S^2(Se_i) = \alpha_i^{1/3} S(Se_i) = \alpha_i^{2/3} Se_i = \alpha_i e_i.$$

Thus, every self-adjoint operator on a real inner product space has a cube root. \square

12 Suppose V is a complex vector space and $T \in \mathcal{L}(V)$ is normal. Prove that if S is an operator on V that commutes with T , then S commutes with T^* .

Solution:

Suppose T is normal and S commutes with T . From *Problem 7B.9* we know that there exists a polynomial $p(T)$ such that $T^* = p(T)$. Now we have:

$$ST^* = Sp(T) = p(T)S = T^*S,$$

where the second equation holds because S commutes with T . \square

13 Without using the complex spectral theorem, use the version of Schur's theorem that applies to two commuting operators (take $\mathcal{E} = \{T, T^*\}$ in *Problem 6B.20*) to give a different proof that if $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is normal, then T has a diagonal matrix with respect to some orthonormal basis of V .

Solution:

Let V be a complex inner product space and $T \in \mathcal{L}(V)$ be a normal operator. Taking a subspace $\mathcal{E} = \{T, T^*\}$ of $\mathcal{L}(V)$ of commuting operators, we have that by extension of Schur's theorem (*Problem 6B.20*), there exists an orthonormal basis of V , with respect to which both T and T^* have an upper-triangular matrix.

Matrix of T^* (with respect to the chosen basis) is a conjugate transpose of the matrix of T , hence $\mathcal{M}(T^*)$ is lower-triangular. As $\mathcal{M}(T^*)$ is simultaneously upper-triangular and lower-triangular, it must be diagonal. Hence, matrix of T is also diagonal, as desired. \square

14 Suppose $\mathbb{F} = \mathbb{R}$ and $T \in \mathcal{L}(V)$. Prove that T is self-adjoint if and only if all pairs of eigenvectors corresponding to distinct eigenvalues of T are orthogonal and $V = E(\lambda_1, T) \oplus \cdots \oplus E(\lambda_m, T)$, where $\lambda_1, \dots, \lambda_m$ denote the distinct eigenvalues of T .

Solution:

We have:

$$T \text{ is self-adjoint} \iff T \text{ is diagonalizable} \iff V = E(\lambda_1, T) \oplus \cdots \oplus E(\lambda_m, T),$$

where the first equivalence is due to Real Spectral Theorem (7.29). The second equivalence is due to Theorem 5.55, where we also use the property that all pairs of eigenvectors corresponding to distinct eigenvalues of T are orthogonal. When coming from T being self-adjoint it follows naturally as a property of normal, here specifically self-adjoint, operators (Theorem 7.22). When going in the other direction, this property ensures that the basis can be chosen orthonormal (in order to use Spectral Theorem), as vectors from

different eigenspaces are orthogonal and vectors within an eigenspace can be orthogonalized via Gram-Schmidt procedure. \square

15 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Prove that T is normal if and only if all pairs of eigenvectors corresponding to distinct eigenvalues of T are orthogonal and $V = E(\lambda_1, T) \oplus \cdots \oplus E(\lambda_m, T)$, where $\lambda_1, \dots, \lambda_m$ denote the distinct eigenvalues of T .

Solution:

We have:

$$T \text{ is normal} \iff T \text{ is diagonalizable} \iff V = E(\lambda_1, T) \oplus \cdots \oplus E(\lambda_m, T),$$

where the first equivalence is due to Complex Spectral Theorem (7.31). The second equivalence is due to Theorem 5.55, where we also use the property that all pairs of eigenvectors corresponding to distinct eigenvalues of T are orthogonal. When coming from T being normal adjoint it follows naturally as a property of normal operators (Theorem 7.22). When going in the other direction, this property ensures that the basis can be chosen orthonormal (in order to use Spectral Theorem), as vectors from different eigenspaces are orthogonal and vectors within an eigenspace can be orthogonalized via Gram-Schmidt procedure. \square

16 Suppose $\mathbb{F} = \mathbb{C}$ and $\mathcal{E} \subseteq \mathcal{L}(V)$. Prove that there is an orthonormal basis of V with respect to which every element of \mathcal{E} has a diagonal matrix if and only if S and T are commuting normal operators for all $S, T \in \mathcal{E}$.

Solution:

If there exists an orthonormal basis of V with respect to which every element of \mathcal{E} has a diagonal matrix, then the conclusion follows directly, as any diagonalizable operators commute, and because they are diagonalizable with respect to the orthonormal basis, these operators are normal (Spectral Theorem).

Now suppose that for any $S, T \in \mathcal{E}$, S and T are commuting normal operators. *Problem 6B.20* implies that there exists an orthonormal basis of V with respect to which every element of \mathcal{E} has an upper-triangular matrix.

Suppose $T \in \mathcal{E}$. By the conclusion above, it has an upper-triangular matrix with respect to the chosen orthonormal basis. We will show that this matrix is actually a diagonal matrix.

As in the proof of the complex spectral theorem, we see that

$$\begin{aligned} \|Te_1\|^2 &= |a_{1,1}|^2, \\ \|T^*e_1\|^2 &= |a_{1,1}|^2 + |a_{1,2}|^2 + \cdots + |a_{1,n}|^2. \end{aligned}$$

Because T is normal, $\|Te_1\| = \|T^*e_1\|$. Thus the two equations above imply that all entries in the first row of the matrix of T , except possibly the first entry $a_{1,1}$, equal zero. This, in turn, implies that

$$\begin{aligned}\|Te_2\|^2 &= |a_{2,2}|^2, \quad \text{because we showed that } a_{1,2} = 0, \\ \|T^*e_2\|^2 &= |a_{2,2}|^2 + |a_{2,3}|^2 + \cdots + |a_{2,n}|^2.\end{aligned}$$

Because T is normal, $\|Te_2\| = \|T^*e_2\|$. Thus, the two equations above imply that all entries in the second row of the matrix of T , except possibly the first entry $a_{2,2}$, equal zero.

Continuing in this fashion, we see that all non-diagonal entries in the matrix of T equal 0. As it holds for any operator in \mathcal{E} , we actually showed that the chosen basis is indeed the orthonormal basis with respect to which every element of \mathcal{E} has a diagonal matrix. \square

17 Suppose $\mathbb{F} = \mathbb{R}$ and $\mathcal{E} \subseteq \mathcal{L}(V)$. Prove that there is an orthonormal basis of V with respect to which every element of \mathcal{E} has a diagonal matrix if and only if S and T are commuting self-adjoint operators for all $S, T \in \mathcal{E}$.

Solution:

If there exists an orthonormal basis of V with respect to which every element of \mathcal{E} has a diagonal matrix, then the conclusion follows directly, as any diagonalizable operators commute, and because they are diagonalizable with respect to the orthonormal basis, these operators are self-adjoint (Spectral Theorem).

Now suppose that for any $S, T \in \mathcal{E}$, S and T are commuting self-adjoint operators. *Problem 6B.20* implies that there exists an orthonormal basis of V with respect which every element of V has an upper-triangular matrix. Let A be a matrix of an operator T with respect to the chosen basis. By Theorem 7.9 (for $\mathbb{F} = \mathbb{C}$), $A^t = A$. We also have $A_{i,j} = A_{j,i}$. This implies that all non-diagonal entries of A equal zero. Hence, all elements of \mathcal{E} have a diagonal matrix with respect to the chosen orthonormal basis. \square

18 Give an example of a real inner product space V , an operator $T \in \mathcal{L}(V)$, and real numbers b, c with $b^2 < 4c$ such that

$$T^2 + bT + cI$$

is not invertible.

Solution:

Let $V = \mathbb{R}^2$ and take T such that with respect to the standard basis its matrix is

$$\mathcal{M}(T) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Now take $b = 0$ and $c = 1$ ($b^2 < 4c$). We have

$$\begin{aligned} \mathcal{M}(T^2 + bT + cI) &= \mathcal{M}(T^2 + I) = \mathcal{M}(T^2) + \mathcal{M}(I) \\ &= \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \end{aligned}$$

Hence, $T^2 + I = 0$, which is not invertible, as desired. \square

19 Suppose $T \in \mathcal{L}(V)$ is self-adjoint and U is a subspace of V that is invariant under T .

- (a) Prove that U^\perp is invariant under T .
- (b) Prove that $T|_U \in \mathcal{L}(U)$ is self-adjoint.
- (c) Prove that $T|_{U^\perp} \in \mathcal{L}(U^\perp)$ is self-adjoint.

Solution:

(a) By the result of *Problem 7A.4*, U^\perp is invariant under T^* . Here T is self-adjoint, i.e. $T^* = T$, which implies U^\perp is invariant under T .

(b) Let $u_1, u_2 \in U$. First treating u_1, u_2 as vectors of V with the inner product defined on V , we have

$$\langle Tu_1, u_2 \rangle = \langle u_1, Tu_2 \rangle,$$

as T is self-adjoint.

Because U is invariant under T , we can treat T in the equation above as $T|_U$ and have inner product on U . Thus, we have

$$\langle T|_U u_1, u_2 \rangle = \langle u_1, T|_U u_2 \rangle.$$

Thus, $T|_U$ is self-adjoint.

(c) Substituting U^\perp for U in the proof above (valid because of the part (a)), we have a proof that $T|_{U^\perp}$ is self-adjoint. \square

20 Suppose $T \in \mathcal{L}(V)$ is normal and U is a subspace of V that is invariant under T .

- (a) Prove that U^\perp is invariant under T .
- (b) Prove that U is invariant under T^* .
- (c) Prove that $(T|_U)^* = (T^*)|_U$.
- (d) Prove that $T|_U \in \mathcal{L}(U)$ and $T|_{U^\perp} \in \mathcal{L}(U^\perp)$ are normal operators.

Solution:

Let u_1, \dots, u_n be an orthonormal basis of U and w_1, \dots, w_m be an orthonormal basis of U^\perp . Then $u_1, \dots, u_n, w_1, \dots, w_m$ is an orthonormal basis of V . The matrix of T with respect to this basis is:

$$\mathcal{M}(T) = \begin{pmatrix} a_{1,1} & \cdots & a_{1,n} & a_{1,n+1} & \cdots & a_{1,n+m} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & \cdots & a_{n,n} & a_{n,n+1} & \cdots & a_{n,n+m} \\ 0 & \cdots & 0 & a_{n+1,n+1} & \cdots & a_{n+1,n+m} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & a_{n+m,n+1} & \cdots & a_{n+m,n+m} \end{pmatrix},$$

where the lower left block is all zeros, because U is invariant under T .

Now consider the sum:

$$\sum_{k=1}^n \|Te_k\|^2 = \sum_{k=1}^n \sum_{j=1}^n |a_{j,k}|^2. \quad (7.6)$$

Because T is normal, we have

$$\sum_{k=1}^n \|Te_k\|^2 = \sum_{k=1}^n \|T^*e_k\|^2$$

Using Theorem 7.9, we obtain

$$\sum_{k=1}^n \|T^*e_k\|^2 = \sum_{k=1}^n \sum_{j=1}^{n+m} |\bar{a}_{k,j}|^2 = \sum_{k=1}^n \sum_{j=1}^{n+m} |a_{k,j}|^2 \quad (7.7)$$

Now subtracting 7.6 from 7.7 (with interchanged dummy indices), we get

$$\sum_{k=1}^n \sum_{j=n+1}^{n+m} |a_{k,j}|^2 = 0.$$

This equation holds if and only if $a_{k,j} = 0$ for all $k = 1, \dots, n$ and $j = n+1, \dots, n+m$.

Therefore, the matrix of T has the form

$$\mathcal{M}(T) = \begin{pmatrix} a_{1,1} & \dots & a_{1,n} & 0 & \dots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & \dots & a_{n,n} & 0 & \dots & 0 \\ 0 & \dots & 0 & a_{n+1,n+1} & \dots & a_{n+1,n+m} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & 0 & a_{n+m,n+1} & \dots & a_{n+m,n+m} \end{pmatrix},$$

which proves that U^\perp is invariant under T and (upon taking the complex conjugate transpose of the matrix) that U is invariant under T^\perp .

Comparison of the matrices with respect to the chosen basis proves (c). Matrix of $T|_U$ is the upper left block of the matrix of T ; matrix of $(T|_U)^*$ is thus

$$\begin{pmatrix} \bar{a}_{1,1} & \dots & \bar{a}_{n,1} \\ \vdots & \ddots & \vdots \\ \bar{a}_{1,n} & \dots & \bar{a}_{n,n} \end{pmatrix}. \quad (7.8)$$

The matrix of T^* is complex conjugate transpose of T , and matrix of $(T^*)|_U$ is its upper left block, which gives the same matrix as 7.8. Hence, $(T|_U)^* = (T^*)|_U$.

Finally, that $T|_U$ and $T|_{U^\perp}$ are normal follows from the normality of T and that U and U^\perp are invariant under both T and T^* . \square

21 Suppose that T is a self-adjoint operator on a finite-dimensional inner product space and that 2 and 3 are the only eigenvalues of T . Prove that

$$T^2 - 5T + 6I = 0.$$

Solution:

T is self-adjoint and hence by Spectral Theorem, is diagonalizable. Then, by Theorems 5.27 and 5.62, the minimal polynomial of T is $(z-2)(z-3) = z^2 - 5z + 6$, as 2 and 3 are the only eigenvalues of T . By definition of a minimal polynomial:

$$p(T) = T^2 - 5T + 6I = 0. \quad \square$$

22 Give an example of an operator $T \in \mathcal{L}(\mathbb{C}^3)$ such that 2 and 3 are the only eigenvalues of T and $T^2 - 5T + 6I \neq 0$.

Solution:

Take $T \in \mathcal{L}(\mathbb{C}^3)$ such that with respect to the standard basis, its matrix is:

$$\mathcal{M}(T) = \begin{pmatrix} 2 & 1 & 2 \\ 0 & 2 & 1 \\ 0 & 0 & 3 \end{pmatrix}$$

One can then check with the matrix operations, that $T^2 - 5T + 6I \neq 0$:

$$\mathcal{M}(T^2 - 5T + 6I) = \begin{pmatrix} 2 & 1 & 2 \\ 0 & 2 & 1 \\ 0 & 0 & 3 \end{pmatrix}^2 - 5 \begin{pmatrix} 2 & 1 & 2 \\ 0 & 2 & 1 \\ 0 & 0 & 3 \end{pmatrix} + 6 \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

23 Suppose $T \in \mathcal{L}(V)$ is self-adjoint, $\lambda \in \mathbb{F}$, and $\epsilon > 0$. Suppose there exists $v \in V$ such that $\|v\| = 1$ and

$$\|Tv - \lambda v\| < \epsilon.$$

Prove that T has an eigenvalue λ' such that $|\lambda - \lambda'| < \epsilon$.

Solution:

T is self-adjoint, hence by the Spectral Theorem, there exists an orthonormal basis e_1, \dots, e_n of V , with respect to which the matrix of T is diagonal. That means

$$Te_k = \lambda_k e_k,$$

where λ_k is an eigenvalue of T (repetitions are possible).

Now express v via basis vectors:

$$v = a_1 e_1 + \dots + a_n e_n.$$

Here we also have

$$\sum_{k=1}^n |a_k|^2 = 1, \tag{7.9}$$

because $\|v\| = 1$. Now recast the inequality $\|Tv - \lambda v\| < \epsilon$ as $\|Tv - \lambda v\|^2 < \epsilon^2$.

Note that in the left part of the inequality we have

$$\begin{aligned}
\|Tv - \lambda v\|^2 &= \left\| \sum_{k=1}^n a_k \lambda_k e_k - \lambda \sum_{k=1}^n a_k e_k \right\|^2 \\
&= \left\| \sum_{k=1}^n a_k (\lambda_k - \lambda) e_k \right\|^2 \\
&= \sum_{k=1}^n |a_k (\lambda_k - \lambda)|^2 = \sum_{k=1}^n |a_k|^2 |\lambda_k - \lambda|^2 \\
&\geq |\lambda' - \lambda|^2 \sum_{k=1}^n |a_k|^2 \\
&= |\lambda' - \lambda|^2.
\end{aligned}$$

The third equality is valid because the list e_1, \dots, e_n is orthonormal (Theorem 6.24). The last equality is valid because of 7.9. For the inequality we took an eigenvalue λ' of T such that $|\lambda' - \lambda|$ is the smallest amongst $|\lambda_k - \lambda|$. Combining this result with the given inequality we have:

$$|\lambda' - \lambda|^2 < \epsilon^2 \quad \Rightarrow \quad |\lambda - \lambda'| < \epsilon. \quad \square$$

24 Suppose U is a finite-dimensional vector space and $T \in \mathcal{L}(U)$.

- (a) Suppose $\mathbb{F} = \mathbb{R}$. Prove that T is diagonalizable if and only if there is a basis of U such that the matrix of T with respect to this basis equals its transpose.
- (b) Suppose $\mathbb{F} = \mathbb{C}$. Prove that T is diagonalizable if and only if there is a basis of U such that the matrix of T with respect to this basis commutes with its conjugate transpose.

Solution:

(a) First suppose that T is diagonalizable. Then the conclusion follows immediately, as any diagonal matrix equals its transpose.

Now suppose that there exists a basis of U such that the matrix of T with respect to this basis equals its transpose. Denote that matrix as A .

Consider a standard orthonormal basis e_1, \dots, e_n of \mathbb{R}^n where $n = \dim U$. Let $S \in \mathcal{L}(\mathbb{R}^n)$ be such operator that its matrix with respect to the standard basis is A . The transpose of A is a matrix of S^* with respect to the standard basis. By the Real Spectral Theorem, there exists an orthonormal basis of

\mathbb{R}^n consisting of eigenvectors x_1, \dots, x_n of S , such that its matrix is diagonal with respect to that basis. Now we represent eigenvectors x_1, \dots, x_n as column-matrices with respect to the standard basis as:

$$x_j = \begin{pmatrix} x_{j,1} \\ \vdots \\ x_{j,n} \end{pmatrix}.$$

As these vectors are the eigenvectors of S , represented by the matrix A , we have:

$$A \cdot x = \begin{pmatrix} A_{1,1} & A_{1,2} & \dots & A_{1,n} \\ A_{2,1} & A_{2,2} & \dots & A_{2,n} \\ \vdots & & \ddots & \vdots \\ A_{n,1} & A_{n,2} & \dots & A_{n,n} \end{pmatrix} \begin{pmatrix} x_{j,1} \\ x_{j,2} \\ \vdots \\ x_{j,n} \end{pmatrix} = \begin{pmatrix} \sum_i A_{1,i} x_{j,i} \\ \sum_i A_{2,i} x_{j,i} \\ \vdots \\ \sum_i A_{n,i} x_{j,i} \end{pmatrix} = \lambda_j \begin{pmatrix} x_{j,1} \\ x_{j,2} \\ \vdots \\ x_{j,n} \end{pmatrix},$$

where λ_j is an eigenvalue of the corresponding eigenvector. From here we get a useful relation:

$$\sum_i A_{k,i} x_{j,i} = \lambda_j x_{j,k}, \quad (7.10)$$

for every $k = 1, \dots, n$.

Now we go back to U with its basis u_1, \dots, u_n , with respect to which the matrix of T equals A . Construct vectors in U as follows:

$$v_j = \sum_{k=1}^n x_{j,k} u_k,$$

for every $j = 1, \dots, n$. These are the eigenvectors of T . Indeed, we have:

$$\begin{aligned} T v_j &= \sum_{k=1}^n x_{j,k} T u_k = \sum_{k=1}^n x_{j,k} \sum_{l=1}^n A_{l,k} u_l \\ &= \sum_{k,l=1}^n x_{j,k} A_{l,k} u_l = \sum_{l=1}^n \left(\sum_{k=1}^n A_{l,k} x_{j,k} \right) u_l \\ &= \sum_{l=1}^n \lambda_j x_{j,l} u_l \\ &= \lambda_j v_j. \end{aligned}$$

Here in the fifth equality we used (7.10).

Lastly, we need to show that the list v_1, \dots, v_n is linearly independent. Without loss of generality, suppose v_1, \dots, v_s is linearly dependent list (if not, just choose and relabel the vectors that give the linearly dependent list). By definition, it means there exist $a_1, \dots, a_s \in \mathbb{R}$ such that

$$a_1 v_1 + \dots + a_s v_s = 0.$$

Expanding v_j 's as linear combinations of u_i 's we obtain:

$$\sum_{l=1}^s a_l \sum_{k=1}^n x_{l,k} u_k = \sum_{k=1}^n \left(\sum_{l=1}^s a_l x_{l,k} \right) u_k = 0.$$

As u_1, \dots, u_n is basis and hence linearly independent, we get that

$$\sum_{l=1}^s a_l x_{l,k} = 0$$

for every $k = 1, \dots, n$. That, in turn, means the list x_1, \dots, x_s is linearly dependent. That contradict our initial identification of x_1, \dots, x_n as a basis of \mathbb{R}^n . Thus, the list v_1, \dots, v_n is linearly independent and hence is a basis of U . Now we combine it with Theorem 5.55 to get the desired result that T is diagonalizable. \square

(b) First suppose that T is diagonalizable with respect to some basis u_1, \dots, u_n . Matrix of T with respect to this basis is diagonal; hence the conjugate transpose of this matrix is also diagonal. Any two diagonal matrices commute, giving the desired result.

Now suppose that there exists a basis u_1, \dots, u_n of U such that the matrix of T with respect to this basis commutes with its conjugate transpose. Denote this matrix by A .

Here we consider a standard basis e_1, \dots, e_n of \mathbb{C}^n where $n = \dim U$. Let $S \in \mathcal{L}(\mathbb{C}^n)$ be an operator whose matrix with respect to the standard basis is A . The conjugate transpose of A is a matrix of S^* with respect to the standard basis. By the Complex Spectral Theorem, there exists an orthonormal basis of \mathbb{C}^n consisting of eigenvectors x_1, \dots, x_n of S , such that its matrix is diagonal with respect that basis.

The rest of the proof is the same as in the real case of part (a), with appropriate substitution of \mathbb{R} on \mathbb{C} . Thus, T is diagonalizable. \square

25 Suppose that $T \in \mathcal{L}(V)$ and there is an orthonormal basis e_1, \dots, e_n of V consisting of eigenvectors of T , with corresponding eigenvalues $\lambda_1, \dots, \lambda_n$.

Show that if $k \in \{1, \dots, n\}$, then the pseudoinverse T^\dagger satisfies the equation

$$T^\dagger e_k = \begin{cases} \frac{1}{\lambda_k} e_k & \text{if } \lambda_k \neq 0, \\ 0 & \text{if } \lambda_k = 0. \end{cases}$$

Solution:

Relabel vectors of the given orthonormal basis such that vectors e_1, \dots, e_m have all non-zero eigenvalues and e_{m+1}, \dots, e_n have zero as an eigenvalue. Then we have:

$$V = U \oplus U^\perp$$

where $U = E(0, T) = \text{null } T$ and $U^\perp = E(\lambda_1, T) \oplus \dots \oplus E(\lambda_m, T)$. Also note that such representation implies that $\text{range } T = (\text{null } T)^\perp$ (see also *Problem 5D.3*).

First suppose $w \in U$. Then by definition of the pseudoinverse we have

$$T^\dagger w = (T|_{(\text{null } T)^\perp})^{-1} P_{\text{range } T} w = (T|_{(\text{null } T)^\perp})^{-1} P_{(\text{null } T)^\perp} w = 0.$$

Now examine U^\perp . The operator $T|_{U^\perp}$ is invertible and diagonalizable. By the result of *Problem 5D.7*, an eigenspace of $T|_{U^\perp}$ of an eigenvalue λ_j is an eigenspace of $(T|_{U^\perp})^{-1}$ of eigenvalue $1/\lambda_j$.

If $w \in U^\perp$, then $P_{\text{range } T} w = P_{U^\perp} w = w$. That concludes the proof giving the desired

$$T^\dagger e_k = \begin{cases} \frac{1}{\lambda_k} e_k & \text{if } \lambda_k \neq 0, \\ 0 & \text{if } \lambda_k = 0. \end{cases} \quad \square$$

7C Positive Operators

1 Suppose $T \in \mathcal{L}(V)$. Prove that if both T and $-T$ are positive operators, then $T = 0$.

Solution:

We have for every $v \in V$:

$$0 = \langle 0v, v \rangle = \langle (T - T)v, v \rangle = \langle Tv, v \rangle + \langle (-T)v, v \rangle.$$

Sum of two nonnegative terms equal zero, hence each of the terms also equals zero. Thus, we have that T is self-adjoint (by definition of positive operator) and $\langle Tv, v \rangle = 0$ for every $v \in V$. That implies $T = 0$, by Theorem 7.16, as desired. \square

2 Suppose $T \in \mathcal{L}(\mathbb{F}^4)$ is the operator whose matrix (with respect to the standard basis) is

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}.$$

Show that T is an invertible positive operator.

Solution:

Let $v \in \mathbb{F}^4$ and $v = a_1e_1 + a_2e_2 + a_3e_3 + a_4e_4$. T acting on v gives

$$Tv = (2a_1 - a_2)e_1 + (-a_1 + 2a_2 - a_3)e_2 + (-a_2 + 2a_3 - a_4)e_3 + (-a_3 + 2a_4)e_4$$

Note, that T is surjective, hence by Theorem 3.63, T is invertible.

The inner product $\langle Tv, v \rangle$ equals

$$\begin{aligned} \langle Tv, v \rangle &= \overline{a_1}(2a_1 - a_2) + (-a_1 + 2a_2 - a_3)\overline{a_2} \\ &\quad + (-a_2 + 2a_3 - a_4)\overline{a_3} + (-a_3 + 2a_4)\overline{a_4} \\ &= 2|a_1|^2 - \overline{a_1}a_2 - a_1\overline{a_2} + 2|a_2|^2 - \overline{a_2}a_3 - a_2\overline{a_3} \\ &\quad + 2|a_3|^2 - \overline{a_3}a_4 - a_3\overline{a_4} + 2|a_4|^2 \\ &= |a_1|^2 + |a_4|^2 + |a_1 - a_2|^2 + |a_2 - a_3|^2 + |a_3 - a_4|^2 \\ &\geq 0. \end{aligned}$$

This shows that T is a positive operator, thus completing the proof. \square

3 Suppose n is a positive integer and $T \in \mathcal{L}(\mathbb{F}^n)$ is the operator whose matrix (with respect to the standard basis) consists of all 1's. Show that T is a positive operator.

Solution:

Let $v = a_1e_1 + \cdots + a_ne_n$. Then:

$$Tv = (a_1 + \cdots + a_n)e_1 + \cdots (a_1 + \cdots + a_n)e_n.$$

The inner product $\langle Tv, v \rangle$ equals

$$\begin{aligned}
\langle Tv, v \rangle &= \overline{a_1}(a_1 + \cdots + a_n) + \cdots + \overline{a_n}(a_1 + \cdots + a_n) \\
&= |a_1|^2 + \overline{a_1}a_2 + \cdots + \overline{a_1}a_n \\
&\quad + |a_2|^2 + \overline{a_2}a_1 + \cdots + \overline{a_2}a_n + \cdots \\
&\quad + |a_n|^2 + \overline{a_n}a_2 + \cdots + \overline{a_n}a_{n-1} \\
&= \sum_{i=1}^n |a_i|^2 + 2 \sum_{i=1}^{n-1} \sum_{k=i+1}^n \Re a_i a_k \\
&= |a_1 + \cdots + a_n|^2 \\
&\geq 0
\end{aligned}$$

hence the operator T is a positive operator. \square

4 Suppose n is an integer with $n > 1$. Show that there exists an n -by- n matrix A such that all of the entries of A are positive numbers and $A = A^*$, but the operator on \mathbb{F}^n whose matrix (with respect to the standard basis) equals A is not a positive operator.

Solution:

Referring to Theorem 7.38, we see that we should look for an operator T (with matrix A) which has at least one negative eigenvalue. The following matrix confirms to this criterion:

$$A = \begin{pmatrix} 1 & 2 & 5 \\ 2 & 1 & 2 \\ 5 & 2 & 1 \end{pmatrix}.$$

This is a symmetric matrix, hence it equals its complex conjugate transpose.

This operator has a negative eigenvalue -4 with eigenvector $v = (1, 0, -1)$. Hence, for this vector we have:

$$\langle Tv, v \rangle = \langle -4(1, 0, -1), (1, 0, -1) \rangle = -8 < 0.$$

So, T is not a positive operator, as desired. \square

5 Suppose $T \in \mathcal{L}(V)$ is self-adjoint. Prove that T is a positive operator if and only if for every orthonormal basis e_1, \dots, e_n of V , all entries on the diagonal of $\mathcal{M}(T, (e_1, \dots, e_n))$ are nonnegative numbers.

Solution:

For any orthonormal basis, entries on the diagonal of a matrix equal the inner product $\langle Te_j, e_j \rangle$.

If T is a positive operator, then $\langle Te_j, e_j \rangle \geq 0$ regardless of a chosen basis.

Going in the other direction, if all entries on the diagonal of the matrix of T are nonnegative for every orthonormal basis, then we can choose an orthonormal basis, with respect to which T is diagonal (we can do that by the Spectral Theorem). All entries on the diagonal are thus nonnegative and by Theorem 7.38, it follows that T is a positive operator. \square

6 Prove that the sum of two positive operators on V is a positive operator.

Solution:

Suppose $T, S \in \mathcal{L}(V)$ are both positive operators. Then for $T+S$ we have:

$$\langle (T+S)v, v \rangle = \langle Tv, v \rangle + \langle Sv, v \rangle \geq 0,$$

where the first equality is true because an inner product has additivity in first slot, and the inequality holds because each term in the sum is nonnegative. Thus, the sum of two positive operators is a positive operator. \square

7 Suppose $S \in \mathcal{L}(V)$ is an invertible positive operator and $T \in \mathcal{L}(V)$ is a positive operator. Prove that $S+T$ is invertible.

Solution:

Suppose $S+T$ is not invertible. That means (Theorem 3.65) $S+T$ is not injective. Let $v \in V$ is a nonzero vector such that $(S+T)v = 0$. Then:

$$Sv = -Tv,$$

Now we take an inner product of both parts with $v \neq 0$.

$$\langle Sv, v \rangle \geq 0, \quad \text{because } S \text{ is a positive operator.}$$

$$\langle -Tv, v \rangle = -\langle Tv, v \rangle \leq 0, \quad \text{because } T \text{ is a positive operator.}$$

These inequalities can be true simultaneously only if $Tv = Sv = 0$. That cannot be, as S is an invertible, hence an injective operator, and $Sv = 0$ if and only if $v = 0$, which is not the case here.

Thus, our assumption that $S+T$ is not invertible is false, thus proving the proposition. \square

8 Suppose $T \in \mathcal{L}(V)$. Prove that T is a positive operator if and only if the pseudoinverse T^\dagger is a positive operator.

Solution:

First suppose that T is positive. Then by Theorem 7.38, there is an orthonormal basis e_1, \dots, e_n of V consisting of eigenvectors of T with eigenvalues $\lambda_1, \dots, \lambda_n$. By the result of *Problem 7B.25*, the pseudoinverse satisfies the equation:

$$T^\dagger e_k = \begin{cases} \frac{1}{\lambda_k} e_k & \text{if } \lambda_k \neq 0, \\ 0 & \text{if } \lambda_k = 0. \end{cases}$$

One can see that T^\dagger is diagonalizable with respect to the basis e_1, \dots, e_n with only nonnegative numbers on the diagonal (i.e. eigenvalues). Thus, T^\dagger is a positive operator, by Theorem 7.38.

Now suppose that T^\dagger is a positive operator. It means it is a self-adjoint and hence a normal operator. This implies that $V = \text{null } T^\dagger \oplus \text{range } T^\dagger$ (Theorem 7.21), and $\text{range } T^\dagger = (\text{null } T^\dagger)^\perp$ and $\text{null } T^\dagger = (\text{range } T^\dagger)^\perp$ (Theorem 7.6).

Using the result of *Problem 6C.20*, we can deduce the following:

$$\begin{aligned} \text{range } T^\dagger &= (\text{null } T^\dagger)^\perp = ((\text{range } T)^\perp)^\perp = \text{range } T \\ \text{null } T^\dagger &= (\text{range } T^\dagger)^\perp = ((\text{null } T)^\perp)^\perp = \text{null } T. \end{aligned}$$

Now any $v \in V$ can be represented as $v = u + w$, where $u \in \text{null } T = \text{null } T^\dagger$ and $w \in \text{range } T = \text{range } T^\dagger$.

For $u \in \text{null } T$ we have $Tu = 0$, hence $\langle Tu, u \rangle = 0$.

For $w \in \text{range } T^\dagger = (\text{null } T)^\perp$ we have a unique element of $y \in \text{range } T$ such that $T^\dagger y = w$. As T^\dagger is positive, we have:

$$\langle T^\dagger y, y \rangle \geq 0 \Rightarrow \langle w, Tw \rangle \geq 0 \Rightarrow \langle Tw, w \rangle \geq 0.$$

Now we have for any $v \in V$:

$$\begin{aligned} \langle Tv, v \rangle &= \langle Tu + Tw, u + w \rangle = \langle Tw, u + w \rangle \\ &= \langle Tw, u \rangle + \langle Tw, w \rangle \\ &= \langle Tw, w \rangle \\ &\geq 0 \end{aligned}$$

where we used $\langle Tw, u \rangle = 0$ in the last equality, because $Tw \in \text{range } T = (\text{null } T)^\perp$ and $u \in \text{null } T$, so Tw and u are orthogonal.

We have shown that if T^\dagger is a positive operator, then T is also a positive operator, thus completing the proof. \square

9 Suppose $T \in \mathcal{L}(V)$ is a positive operator and $S \in \mathcal{L}(W, V)$. Prove that S^*TS is a positive operator on W .

Solution:

Let $w \in W$. Then we have:

$$\langle S^*TSw, w \rangle = \langle T(Sw), Sw \rangle \geq 0.$$

The first equality comes from the definition of an adjoint, the second equality comes from T being a positive operator. Thus, S^*TS is a positive operator on W . \square

10 Suppose T is a positive operator on V . Suppose $v, w \in V$ are such that

$$Tv = w \quad \text{and} \quad Tw = v.$$

Prove that $v = w$.

Solution:

Examine the following:

$$\begin{aligned} \langle T(v - w), v - w \rangle &= \langle Tv, v \rangle - \langle Tw, v \rangle - \langle Tv, w \rangle + \langle Tw, w \rangle \\ &= \langle w, v \rangle - \langle v, v \rangle - \langle w, w \rangle + \langle v, w \rangle \\ &= 2\Re\langle v, w \rangle - \|v\|^2 - \|w\|^2 \\ &\leq |\langle v, w \rangle| - \|v\|^2 - \|w\|^2 \\ &\leq 2\|v\|\|w\| - \|v\|^2 - \|w\|^2 \\ &= -(\|v\| - \|w\|)^2 \\ &\leq 0. \end{aligned}$$

Here the transition from the fourth to the fifth line is due to the Cauchy-Schwarz inequality (6.14).

On the other hand, T is a positive operator, so

$$\langle T(v - w), v - w \rangle \geq 0.$$

Thus we conclude that $\langle T(v - w), v - w \rangle = 0$.

From the Theorem 7.43 it follows that $T(v - w) = 0$. On the other hand:

$$T(v - w) = Tv - Tw = w - v.$$

Hence, $w - v = 0$, or $v = w$. \square

11 Suppose T is a positive operator on V and U is a subspace of V invariant under T . Prove that $T|_U \in \mathcal{L}(U)$ is a positive operator on U .

Solution:

As U is invariant under T , the inner product $\langle T|_U u, u \rangle_U$ defined on U makes sense. Thus for every $u \in U \subseteq V$ we have:

$$\langle T|_U u, u \rangle_U = \langle Tu, u \rangle_V \geq 0.$$

So $T|_U$ is a positive operator. \square

12 Suppose $T \in \mathcal{L}(V)$ is a positive operator. Prove that T^k is a positive operator for every positive integer k .

Solution:

T is a positive operator, hence it is self-adjoint (Theorem 7.38). We will prove this problem by induction.

Base case: T and T^2 are positive operators. T is given being a positive operator. As for T^2 , we have

$$\langle T^2 v, v \rangle = \langle Tv, T^* v \rangle = \langle Tv, Tv \rangle = \|Tv\|^2 \geq 0,$$

where we use the fact that T is self-adjoint in the second equality. That shows that the base case is true.

Now suppose T^k is positive for some positive integer k . Then

$$\langle T^{k+2} v, v \rangle = \langle T^{k+1} v, T^* v \rangle = \langle T^k(Tv), Tv \rangle \geq 0,$$

so T^k is a positive operator implies that T^{k+2} is a positive operator. That combined with the base case implies that T^k is a positive operator for every positive integer k . \square

13 Suppose $T \in \mathcal{L}(V)$ is self-adjoint and $\alpha \in \mathbb{R}$.

- (a) Prove that $T - \alpha I$ is a positive operator if and only if α is less than or equal to every eigenvalue of T .
- (b) Prove that $\alpha I - T$ is a positive operator if and only if α is greater than or equal to every eigenvalue of T .

Solution:

(a) According to Theorem 7.38, an operator is positive if and only if all its eigenvalues are nonnegative. Operator αI is diagonal in every basis, hence T and αI are simultaneously diagonalizable and thus they commute. By

Theorem 5.81, each eigenvalue of $T - \alpha I$ is an eigenvalue of T minus an eigenvalue of αI . The only eigenvalue of αI is α . Thus for each eigenvalue λ_i of T we have

$$T - \alpha I \text{ is a positive operator} \iff \lambda_i - \alpha \geq 0 \iff \lambda_i \geq \alpha. \quad \square$$

(b) Similarly to (a), we have for each eigenvalue λ_i of T :

$$\alpha I - T \text{ is a positive operator} \iff \alpha - \lambda_i \geq 0 \iff \alpha \geq \lambda_i. \quad \square$$

14 Suppose T is a positive operator on V and $v_1, \dots, v_m \in V$. Prove that

$$\sum_{j=1}^m \sum_{k=1}^m \langle T v_k, v_j \rangle \geq 0.$$

Solution:

Using the additivity in both slots of an inner product we have:

$$\begin{aligned} \sum_{j=1}^m \sum_{k=1}^m \langle T v_k, v_j \rangle &= \langle T v_k, \sum_{j=1}^m v_j \rangle \\ &= \left\langle \sum_{k=1}^m T v_k, \sum_{j=1}^m v_j \right\rangle \\ &= \left\langle \sum_{j=1}^m T v_j, \sum_{j=1}^m v_j \right\rangle \\ &\geq 0. \end{aligned}$$

Where we relabelled dummy indices in the last equality, thus obtaining an expression of $\langle T v, v \rangle$ type and producing the desired inequality. \square

15 Suppose $T \in \mathcal{L}(V)$ is self-adjoint. Prove that there exist positive operators $A, B \in \mathcal{L}(V)$ such that

$$T = A - B \quad \text{and} \quad \sqrt{T^* T} = A + B \quad \text{and} \quad AB = BA = 0.$$

Solution:

Denote $\sqrt{T^* T}$ as S . Then we can construct operators A and B as follows:

$$A = \frac{T + S}{2}, \quad B = \frac{S - T}{2}.$$

These operators satisfy the first two properties. We need to show that they are positive and their composition is zero.

Take an orthonormal basis e_1, \dots, e_n of V with respect to which T is diagonal. All diagonal entries of T , i.e. eigenvalues, are real (Theorem 7.12). Now note that $S^2 = T^*T$ has the same eigenvectors with eigenvalues $\lambda_1^2, \dots, \lambda_n^2$. Its positive square root S also has eigenvectors e_1, \dots, e_n , but with eigenvalues $|\lambda_1|, \dots, |\lambda_n|$.

Using the rule of matrix summation, we have that the matrices of A and B are diagonal with entries being equal:

$$\mathcal{M}(A)_{j,j} = \frac{\lambda_j + |\lambda_j|}{2}, \quad \mathcal{M}(B)_{j,j} = \frac{|\lambda_j| - \lambda_j}{2}.$$

If $\lambda_j \geq 0$, $\mathcal{M}(A)_{j,j} = \lambda_j$ and $\mathcal{M}(B)_{j,j} = 0$.

If $\lambda_j < 0$, $\mathcal{M}(A)_{j,j} = 0$ and $\mathcal{M}(B)_{j,j} = |\lambda_j|$.

Thus, A and B have diagonal matrices with respect to the orthonormal basis e_1, \dots, e_n with only nonnegative numbers on the diagonal. It means that A and B are positive operators (Theorem 7.38).

At last we have:

$$\begin{aligned} AB &= \frac{T+S}{2} \frac{S-T}{2} = \frac{1}{4}(TS - T^2 + S^2 - ST) = \frac{1}{4}(T^*T - T^2) = 0 \\ BA &= \frac{S-T}{2} \frac{T+S}{2} = \frac{1}{4}(ST + S^2 - T^2 - TS) = \frac{1}{4}(T^*T - T^2) = 0. \end{aligned}$$

Here we used the fact that S and T commute (they are simultaneously diagonalizable) and that T is self-adjoint. \square

16 Suppose T is a positive operator on V . Prove that

$$\text{null } \sqrt{T} = \text{null } T \quad \text{and} \quad \text{range } \sqrt{T} = \text{range } T.$$

Solution:

Let $R = \sqrt{T}$, hence $T = R^2$. R is self-adjoint (Theorem 7.38), hence it is normal. By the result of *Problem 7A.27*

$$\text{null } R = \text{null } R^2 \quad \text{and} \quad \text{range } R = \text{range } R^2,$$

proving the desired result. \square

17 Suppose that $T \in \mathcal{L}(V)$ is a positive operator. Prove that there exists a polynomial p with real coefficients such that $\sqrt{T} = p(T)$.

Solution:

Let $\lambda_1, \dots, \lambda_m$ be distinct eigenvalues of T . Then $p(T)$ and \sqrt{T} have the same eigenvectors, but with eigenvalues $p(\lambda_1), \dots, p(\lambda_m)$ and $\sqrt{\lambda_1}, \dots, \sqrt{\lambda_m}$. We need that for every $j = 1, \dots, m$

$$p(\lambda_j) = \sqrt{\lambda_j}.$$

$\lambda_j, \sqrt{\lambda_j} \in \mathbb{R}$ for every $j = 1, \dots, m$. Thus, by the result of *Problem 4.7*, there exists a unique polynomial $p \in \mathcal{P}_{m-1}(\mathbb{R})$ satisfying the equation above. That is the sought polynomial $p(T) = \sqrt{T}$ (take an orthonormal basis that diagonalizes T and use linear map lemma 3.4). \square

18 Suppose S and T are positive operators on V . Prove that ST is a positive operator if and only if S and T commute.

Solution:

First suppose that ST is a positive operator. Thus, we have that T, S and ST are self-adjoint operators. Now it is easy to show that S and T commute:

$$ST = (ST)^* = T^*S^* = TS.$$

Now suppose S and T commute. Rearranging the sequence of equalities above we can first show that ST is self-adjoint:

$$ST = TS = T^*S^* = (ST)^*.$$

As S and T are commuting self-adjoint operators, they are simultaneously diagonalizable. Now the ST is also a diagonal matrix with entries on the diagonal being equal to a product of corresponding diagonal entries of S and T . Thus, the matrix of ST (with respect to the same basis) has all nonnegative diagonal entries, which means ST is a positive operator. \square

19 Show that the identity operator on \mathbb{F}^2 has infinitely many self-adjoint square roots.

Solution:

Take a standard orthonormal basis of \mathbb{F}^2 . A self-adjoint square root of the identity operator have the matrix with respect to this basis in the following form:

$$\mathcal{M}(\sqrt{I}) = \begin{pmatrix} \alpha & \beta \\ \bar{\beta} & \gamma \end{pmatrix}.$$

As it is a square root of the identity operator we must have $\mathcal{M}(I) = \mathcal{M}(\sqrt{I})\mathcal{M}(\sqrt{I})$. Thus:

$$\mathcal{M}(\sqrt{I}) = \begin{pmatrix} \alpha & \beta \\ \bar{\beta} & \gamma \end{pmatrix} \cdot \begin{pmatrix} \alpha & \beta \\ \bar{\beta} & \gamma \end{pmatrix} = \begin{pmatrix} \alpha^2 + |\beta|^2 & (\alpha + \gamma)\beta \\ (\alpha + \gamma)\bar{\beta} & \gamma^2 + |\beta|^2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Now we have two options: $\beta = 0$ or $\beta \neq 0$. If $\beta = 0$, then $\alpha = \pm 1$ and $\gamma = \pm 1$. If $\beta \neq 0$, then we must have $\alpha = -\gamma$, and β is determined from $\alpha + |\beta|^2 = 1$. Without loss of generality, assume $\beta \in \mathbb{R}$. Then pairs (α, β) and (γ, β) correspond to points (x, y) and $(-x, y)$ on the unit circle of \mathbb{R}^2 . These points determine the matrix elements of $\mathcal{M}(\sqrt{I})$ and thus determine the operator \sqrt{I} . There are infinitely many such points, therefore there are infinitely many self-adjoint square roots of the identity operator. \square

20 Suppose $T \in \mathcal{L}(V)$ and e_1, \dots, e_n is an orthonormal basis of V . Prove that T is a positive operator if and only if there exist $v_1, \dots, v_n \in V$ such that

$$\langle Te_k, e_j \rangle = \langle v_k, v_j \rangle$$

for all $j, k = 1, \dots, n$.

Solution:

First suppose that T is a positive operator. Then $T = R^*R$ for some $R \in \mathcal{L}(V)$ (Theorem 7.38). Then for all $j, k = 1, \dots, n$ we have:

$$\langle Te_k, e_j \rangle = \langle R^*Re_k, e_j \rangle = \langle Re_k, Re_j \rangle.$$

Take $v_j = Rv_j$ for each $j \in \{1, \dots, n\}$. That is the desired list $v_1, \dots, v_n \in V$.

Now suppose there exist $v_1, \dots, v_n \in V$ such that

$$\langle Te_k, e_j \rangle = \langle v_k, v_j \rangle$$

for all $j, k = 1, \dots, n$. Let $v = a_1e_1 + \dots + a_ne_n$ for some $a_1, \dots, a_n \in \mathbb{F}$. Then we have:

$$\begin{aligned}
\langle Tv, v \rangle &= \left\langle T \sum_k^n a_k e_k, \sum_j^n a_j e_j \right\rangle = \left\langle \sum_k^n a_k T e_k, \sum_j^n a_j e_j \right\rangle \\
&= \sum_k^n a_k \left\langle T e_k, \sum_j^n a_j e_j \right\rangle = \sum_k^n a_k \sum_j^n \overline{a_j} \langle T e_k, e_j \rangle \\
&= \sum_k^n a_k \sum_j^n \overline{a_j} \langle v_k, v_j \rangle \\
&= \sum_k^n a_k \left\langle v_k, \sum_j^n a_j v_j \right\rangle = \left\langle \sum_k^n a_k v_k, \sum_j^n a_j v_j \right\rangle \\
&= \left\| \sum_k^n a_k v_k \right\|^2 \geq 0.
\end{aligned}$$

Thus, T is a positive operator, which completes the proof. \square

21 Suppose n is a positive integer. The n -by- n *Hilbert matrix* is the n -by- n matrix whose entry in row j , column k is $\frac{1}{j+k-1}$. Suppose $T \in \mathcal{L}(V)$ is an operator whose matrix with respect to some orthonormal basis of V is the n -by- n Hilbert matrix. Prove that T is a positive invertible operator.

Solution:

Here we use the fact that $\langle T e_k, e_j \rangle$ is an entry in the matrix of T at k 'th column, j 'th row. We need to find $v_1, \dots, v_n \in V$ such that the condition of *Problem 7C.20* holds; that will prove that T is a positive operator.

Take $\mathcal{P}_{n-1}(\mathbb{F})$, which is isomorphic to V . We will make (an arbitrary!) correspondence between the orthonormal basis e_1, \dots, e_n of V and an orthonormal basis of $\mathcal{P}_{n-1}(\mathbb{F})$ (obtained, for example, by Gram-Schmidt procedure from the standard $1, x, x^2, \dots$ basis). That will define a map $S : V \rightarrow \mathcal{P}_{n-1}(\mathbb{F})$ (linear map lemma 3.4), that is our 'correspondence' between V and $\mathcal{P}_{n-1}(\mathbb{F})$.

Let us define the inner product on V in such a way that it corresponds to an inner product on $\mathcal{P}_{n-1}(\mathbb{F})$:

$$\langle v, w \rangle = \langle Sv, Sw \rangle = \int_0^1 pq$$

where $v, w \in V$, and $p = Sv$, $q = Sw$.

S is a surjective map, hence it is invertible. Choose $v_1, \dots, v_n \in V$ such

that $v_k = S^{-1}(x^k)$. Now we have:

$$\begin{aligned}\langle v_j, v_k \rangle &= \langle x^j, x^k \rangle \\ &= \int_0^1 x^j x^k dx = \int_0^1 x^{j+k} dx \\ &= \frac{1}{j+k-1} \\ &= \langle Te_j, e_k \rangle.\end{aligned}$$

Thus, T is a positive operator. We need to show that T is invertible. Suppose it is not. Then there exists nonzero $v \in V$ such that $Tv = 0$. Then it is also true that $\langle Tv, v \rangle = 0$.

Expressing v via basis vectors, $v = a_1e_1 + \cdots + a_ne_n$, we have:

$$\begin{aligned}\langle Tv, v \rangle &= \langle T \sum_j^n a_j e_j, \sum_k^n a_k e_k \rangle = \sum_j^n a_j \sum_k^n \overline{a_k} \langle Te_j, e_k \rangle \\ &= \sum_j^n a_j \sum_k^n \overline{a_k} \langle v_j, v_k \rangle = \langle \sum_j^n a_j v_j, \sum_k^n v_k \rangle \\ &= \left\| \sum_k^n a_k v_k \right\|^2 \geq 0.\end{aligned}$$

Because of our assumption, $\langle Tv, v \rangle = 0$, it follows that $\sum_k^n a_k v_k = 0$, that is the list v_1, \dots, v_n is not linearly dependent. That contradicts the invertibility of S which must send every linearly independent list to another linearly independent list (see *Problem 3B.9*). Thus, T is an invertible positive operator, as desired. \square

22 Suppose $T \in \mathcal{L}(V)$ is a positive operator and $u \in V$ is such that $\|u\| = 1$ and $\|Tu\| \geq \|Tv\|$ for all $v \in V$ with $\|v\| = 1$. Show that u is an eigenvector of T corresponding to the largest eigenvalue of T .

Solution:

T is a positive operator, hence it is self-adjoint, hence it is diagonalizable by Spectral Theorem. As T is diagonalizable, V is a direct sum of the eigenspaces of T (*Problem 7B.14* and *Problem 7B.15*), $V = E(\lambda_1, T) \oplus \cdots \oplus E(\lambda_m, T)$ and all pairs of eigenvectors corresponding to different eigenvalues are orthogonal. Let λ_n be the largest eigenvalue of these.

We can write u as a sum $u = v_1 + \cdots + v_n$, where each v_j is a unit vector and $v_j \in E(\lambda_j, T)$. We have $\|u\|^2 = \|v_1\|^2 + \cdots + \|v_n\|^2 = 1$, and

$$\begin{aligned}\|Tu\|^2 &= \|\lambda_1 v_1 + \cdots + \lambda_n v_n\|^2 = \lambda_1^2 \|v_1\|^2 + \cdots + \lambda_n^2 \|v_n\|^2 \\ &\leq \lambda_n^2 (\|v_1\|^2 + \cdots + \|v_n\|^2) = \lambda_n^2.\end{aligned}$$

Now let $w_n \in E(\lambda_n, T)$ be a unit vector. We must have $\|Tu\|^2 \geq \|Tw_n\|^2$, so

$$\|Tu\|^2 \geq \|Tw_n\|^2 = \lambda_n^2 \|w_n\|^2 = \lambda_n^2.$$

Thus, we came to the $\lambda_n^2 \leq \|Tu\|^2 \leq \lambda_n^2$. Therefore, $\|Tu\|^2 = \lambda_n^2$. Writing u as a sum of v_1, \dots, v_n one again, we have

$$\begin{aligned}\lambda_1^2 \|v_1\|^2 + \cdots + \lambda_n^2 \|v_n\|^2 &= \lambda_n^2 \\ \lambda_1^2 \|v_1\|^2 + \cdots + \lambda_n^2 (\|v_n\|^2 - 1) &= 0\end{aligned}$$

If the largest eigenvalue is zero, then it is the only eigenvalue of T (eigenvalues of a positive operator must be nonnegative), and the conclusion is obviously true.

If $\lambda_n \neq 0$, then we must have $\|v_j\| = 0$ except for $j = n$, for which $\|v_n\| = 1$. Thus we left with $u = v_n$, so indeed u is an eigenvector of T corresponding to the largest eigenvalue. \square

23 For $T \in \mathcal{L}(V)$ and $u, v \in V$, define $\langle u, v \rangle_T$ by $\langle u, v \rangle_T = \langle Tu, v \rangle$.

- (a) Suppose $T \in \mathcal{L}(V)$. Prove that $\langle \cdot, \cdot \rangle_T$ is an inner product on V if and only if T is an invertible positive operator (with respect to the original inner product $\langle \cdot, \cdot \rangle$).
- (b) Prove that every inner product on V is of the form $\langle \cdot, \cdot \rangle_T$ for some positive invertible operator $T \in \mathcal{L}(V)$.

Solution:

(a) Regardless of what type of operator T is, additivity, homogeneity and conjugate symmetry hold:

$$\begin{aligned}\langle u + w, v \rangle_T &= \langle T(u + w), v \rangle = \langle Tu, v \rangle + \langle Tw, v \rangle = \langle u, v \rangle_T + \langle w, v \rangle_T \\ \langle \lambda u, v \rangle_T &= \langle T(\lambda u), v \rangle = \langle \lambda Tu, v \rangle = \lambda \langle Tu, v \rangle = \lambda \langle u, v \rangle_T \\ \langle u, v \rangle_T &= \langle Tu, v \rangle = \overline{\langle v, Tu \rangle} = \overline{\langle Tv, u \rangle} = \overline{\langle v, u \rangle_T}\end{aligned}$$

We need to show positivity and definiteness.

Positivity condition reads:

$$\langle v, v \rangle_T = \langle Tv, v \rangle \geq 0,$$

which is true for every $v \in V$ if and only if T is a positive operator.

Definiteness condition reads:

$$\langle v, v \rangle_T = \langle Tv, v \rangle = 0 \text{ if and only if } v = 0.$$

As T is a positive operator $\langle Tv, v \rangle = 0$ implies that $Tv = 0$. From here we have:

$$(Tv = 0 \text{ if and only if } v = 0) \iff T \text{ is invertible,}$$

thus completing the proof. \square

(b) Let $\langle \cdot, \cdot \rangle$ be some reference inner product on V and $\langle \cdot, \cdot \rangle_d$ is another inner product on V .

Let ϕ_1, \dots, ϕ_n be a (dual) basis of V' . By the Riesz representation theorem, for each $j \in \{1, \dots, n\}$ there is a unique $v_j \in V$ such that:

$$\phi_j(u) = \langle u, v_j \rangle,$$

for every $u \in V$. Similarly, for each $j \in \{1, \dots, n\}$ there is a unique $w_j \in V$ such that:

$$\phi_j(u) = \langle u, w_j \rangle_d,$$

for every $u \in V$. Lists v_1, \dots, v_n and w_1, \dots, w_n are linearly independent. To show this, suppose they were not. Let $v_m = a_1 v_1 + \dots + a_{m-1} v_{m-1}$ for some nonzero $a_1, \dots, a_{m-1} \in \mathbb{F}$. Then we would have:

$$\begin{aligned} \phi_m(u) &= \langle u, v_m \rangle = \langle u, a_1 v_1 + \dots + a_{m-1} v_{m-1} \rangle \\ &= \overline{a_1} \langle u, v_1 \rangle + \dots + \overline{a_{m-1}} \langle u, v_{m-1} \rangle \\ &= \overline{a_1} \phi_1(u) + \dots + \overline{a_{m-1}} \phi_{m-1}(u) \end{aligned}$$

for every $u \in V$. This cannot be, as ϕ_1, \dots, ϕ_n is a basis, hence is a linearly independent list. Similar reasoning applies to w_1, \dots, w_n . This shows that v_1, \dots, v_n and w_1, \dots, w_n are linearly independent indeed. Moreover, length of these two lists equals $\dim V$, so they are two bases of V . Now define operator T such that $T(v_j) = w_j$. Let $v = a_1 v_1 + \dots + a_n v_n$. We have

$$\begin{aligned} \langle u, v \rangle_d &= \phi(u) = \overline{a_1} \phi_1(u) + \dots + \overline{a_n} \phi_n(u) \\ &= \overline{a_1} \langle u, w_1 \rangle + \dots + \overline{a_n} \langle u, w_n \rangle \\ &= \overline{a_1} \langle u, T v_1 \rangle + \dots + \overline{a_n} \langle u, T v_n \rangle \\ &= \langle u, T v \rangle = \langle T^* u, v \rangle. \end{aligned}$$

Using result of part (a) of this exercise, we have that T^* is an invertible positive operator. That means $T^* = T$, so the T defined above is the sought operator. \square

24 Suppose S and T are positive operators on V . Prove that

$$\text{null}(S + T) = \text{null } S \cap \text{null } T$$

Solution:

First suppose that $v \in \text{null } S$ and $v \in \text{null } T$. Then:

$$(T + S)v = Tv + Sv = 0 + 0 = 0,$$

thus $\text{null } S \cap \text{null } T \subseteq \text{null}(S + T)$.

Now suppose $v \in \text{null}(S + T)$. Examine the following inner product:

$$\langle (S + T)v, v \rangle = 0 = \langle Sv, v \rangle + \langle Tv, v \rangle.$$

S and T are positive operators, hence $\langle Sv, v \rangle$ and $\langle Tv, v \rangle$ are nonnegative numbers. This implies that both of these equal zero, $\langle Sv, v \rangle = 0$ and $\langle Tv, v \rangle = 0$. Theorem 7.43 then implies that $Sv = 0$ and $Tv = 0$, that is $v \in \text{null } S \cap \text{null } T$. Hence, $\text{null } S \cap \text{null } T \subseteq \text{null}(S + T)$.

Combining with inclusion in the other direction, we have the desired equality. \square

25 Let T be the second derivative operator in Exercise 31(b) in Section 7A. Show that $-T$ is a positive operator.

Solution:

Let D denote the derivative operator, and T denote the second derivative operator, as in *Problem 7A.31*.

Note that:

$$-T = -D^2 = (-D)D = D^*D.$$

Now Theorem 7.38 condition (f) implies that $-T$ is a positive operator.

7D Isometries, Unitary Operators, and Matrix Factorization

1 Suppose $\dim V \geq 2$ and $S \in \mathcal{L}(V, W)$. Prove that S is an isometry if and only if Se_1, Se_2 is an orthonormal list in W for every orthonormal list e_1, e_2 of length two in V .

Solution:

Taking any orthonormal list e_1, e_2 we can extend it to a basis of V and then apply Gram-Schmidt procedure to get an orthonormal basis e_1, e_2, \dots, e_n of V . Then S being an isometry and Se_1, Se_2, \dots, Se_n being an orthonormal list in W are equivalent (Theorem 7.49). Se_1, Se_2, \dots, Se_n is an orthonormal list implies Se_1, Se_2 is an orthonormal list. That proves the desired result. \square

2 Suppose $T \in \mathcal{L}(V, W)$. Prove that T is a scalar multiple of an isometry if and only if T preserves orthogonality.

Solution:

First suppose T is a scalar multiple of an isometry $T = \alpha S$, then

$$\langle Tv, Tu \rangle = |\alpha|^2 \langle Sv, Su \rangle = |\alpha|^2 \langle v, u \rangle.$$

This implies $\langle Tv, Tu \rangle = 0$ for every $v, u \in V$ such that $\langle v, u \rangle = 0$.

Now we prove the other direction. If $T = 0$, then it is indeed a scalar multiple of some isometry S : $T = 0 \cdot S$. Later in the proof, we assume that $T \neq 0$.

If $\dim V = 0$, then it is trivially true. The only element of V is 0, and the only linear map is $T(0) = 0$, so the only possible inner product is $\langle T0, T0 \rangle = 0$. So, the orthogonality is preserved anyway, and T is an isometry, by definition.

If $\dim V \geq 1$, let e_1, \dots, e_n be an orthonormal basis of V . Because T preserves orthogonality, we have that $Te_1/\|Te_1\|, \dots, Te_n/\|Te_n\|$ is an orthonormal list in W .

If $\dim V = 1$, then the list constructed above is sufficient for the subsequent proof. If $\dim V > 1$, we show that all $\|Te_j\|$ are equal.

Take an orthogonal linear combination of any two vectors of the orthonormal basis of V , e_j and e_k . Let these two combinations be $e_j + e_k$ and $e_j - e_k$. We have:

$$\langle e_j + e_k, e_j - e_k \rangle = \langle e_j, e_j \rangle - \langle e_j, e_k \rangle + \langle e_k, e_j \rangle - \langle e_k, e_k \rangle = 1 - 0 + 0 - 1 = 0.$$

Now, acting by T on both of these combinations, we have

$$\begin{aligned} \langle T(e_j + e_k), T(e_j - e_k) \rangle &= \langle Te_j, Te_j \rangle - \langle Te_j, Te_k \rangle + \langle Te_k, Te_j \rangle - \langle Te_k, Te_k \rangle \\ &= \|Te_j\|^2 - \|Te_k\|^2, \end{aligned}$$

where we used $\langle Te_j, Te_k \rangle = \langle Te_k, Te_j \rangle = 0$, preservation of orthogonality. At the same time, $\langle T(e_j + e_k), T(e_j - e_k) \rangle = 0$, because $\langle e_j + e_k, e_j - e_k \rangle = 0$. That implies $\|Te_j\|^2 = \|Te_k\|^2$ for any pair e_j, e_k of vectors of the orthonormal basis e_1, \dots, e_n of V .

Hence, all $\|Te_j\|$ are equal. Using this, we define $\alpha = \|Te_j\|$. At the same time this guarantees that all $\|Te_j\|$ are non-zero, because that would mean T is the zero operator, which we have already ruled out.

Now we define a linear map S as

$$Sv = \frac{\langle v, e_1 \rangle}{\alpha} Te_1 + \cdots + \frac{\langle v, e_n \rangle}{\alpha} Te_n,$$

where $v \in V$. By Theorem 7.49, S is an isometry. Multiplying both sides of the equation above by α , we have

$$\alpha Sv = \langle v, e_1 \rangle Te_1 + \cdots + \langle v, e_n \rangle Te_n = Tv,$$

which shows that $T = \alpha S$, proving the desired result. \square

3 (a) Show that the product of two unitary operators on V is a unitary operator. (b) Show that the inverse of a unitary operator on V is a unitary operator.

Solution:

Suppose S and T are unitary operators on V . For the product of S and T we have

$$\begin{aligned}(ST)^*(ST) &= T^*(S^*S)T = T^*T = I \\ (ST)(ST)^* &= S(T^*T)S^* = SS^* = I.\end{aligned}$$

Here we used property 7.5d and Theorem 7.53. That proves ST is a unitary operator (also, by Theorem 7.53).

For the inverse of S , we have

$$\begin{aligned}(S^{-1})^*S^{-1} &= (S^*)^{-1}S^{-1} = (SS^*)^{-1} = I^{-1} = I \\ S^{-1}(S^{-1})^* &= S^{-1}(S^*)^{-1} = (S^*S)^{-1} = I^{-1} = I.\end{aligned}$$

Here the first equality uses property 7.5f, the second equality uses result of *Problem 3D.2* and the third equality uses Theorem 7.53. This proves that the inverse of a unitary operator is a unitary operator. \square

4 Suppose $\mathbb{F} = \mathbb{C}$ and $A, B \in \mathcal{L}(V)$ are self-adjoint. Show that $A + iB$ is unitary if and only if $AB = BA$ and $A^2 + B^2 = I$.

Solution:

First note, that $(A + iB)^* = A - iB$, because A and B are self-adjoint.

$A+iB$ is unitary if and only if $(A+iB)(A+iB)^* = (A+iB)^*(A+iB) = I$, Theorem 7.53. Expanding the brackets, we get

$$\begin{aligned}(A+iB)(A+iB)^* &= (A+iB)(A-iB) = A^2 - iAB + iBA + B^2, \\ (A+iB)^*(A+iB) &= (A-iB)(A+iB) = A^2 + iAB - iBA + B^2.\end{aligned}$$

Now we can write two equations, equivalent to the condition above:

$$\begin{cases} A^2 - iAB + iBA + B^2 = I, \\ A^2 + iAB - iBA + B^2 = I. \end{cases} \quad (7.11)$$

Taking the sum of two equations in 7.11 and dividing by two, we get $A^2 + B^2 = I$; subtracting the first equation from the second in 7.11, we get $AB - BA = 0$, or $AB = BA$.

Following all equivalence relations, we conclude that $A+iB$ is a unitary operator if and only if $AB = BA$ and $A^2 + B^2 = I$, as desired. \square

5 Suppose $S \in \mathcal{L}(V)$. Prove that the following are equivalent.

1. S is a self-adjoint unitary operator.
2. $S = 2P - I$ for some orthogonal projection P on V .
3. There exists a subspace U of V such that $Su = u$ for every $u \in U$ and $Sw = -w$ for every $w \in U^\perp$.

Solution:

First suppose (1) is true. Spectral Theorem (7.29 and 7.31) ensures that there is an orthonormal basis e_1, \dots, e_n of V consisting of eigenvectors of S . Then Theorem 7.12 implies that all eigenvalues of S are real. By Theorem 7.54, every eigenvalue of S has absolute value 1, which implies that eigenvalues of S are either 1 or -1 .

Now let e_1, \dots, e_m be vectors of the orthonormal basis of V corresponding to the eigenvalue 1, and let e_{m+1}, \dots, e_n be vectors of the orthonormal basis corresponding to the eigenvalue -1 . Let $U = \text{span}(e_1, \dots, e_m)$, so that $U^\perp = \text{span}(e_{m+1}, \dots, e_n)$ (this follows from the definition of orthogonal complement).

Let P be an orthogonal projection on U . Examine how $(2P - I)$ acts on the basis vectors. For $k \in \{1, \dots, m\}$, $j \in \{m+1, \dots, n\}$ we have

$$\begin{aligned}(2P - I)e_k &= 2e_k - e_k = e_k = Se_k, \\ (2P - I)e_j &= 0 - e_j = -e_j = Se_j.\end{aligned}$$

By the linear map lemma (3.4), $S = 2P - I$, which proves that (1) implies (2).

Now suppose that (2) is true. Denote by U the subspace of V , on which P is an orthogonal projection, then for every $u \in U$

$$Su = (2P - I)u = 2u - u = u,$$

and for every $w \in U^\perp$

$$Sw = (2P - I)w = 0 - w = -w.$$

That proves (2) implies (3).

Finally, suppose (3) is true. Let u_1, \dots, u_m be an orthonormal basis of U and w_1, \dots, w_n be an orthonormal basis of U^\perp . Then $u_1, \dots, u_m, w_1, \dots, w_n$ is an orthonormal basis of V , with respect to which S has a diagonal matrix. Hence, by Spectral Theorem, S is a self-adjoint operator.

Note that $S^2 = I$:

$$S^2(u + w) = S(u - w) = u + w.$$

Because S is self-adjoint, we can write $S^2 = SS^* = S^*S = I$, which means S is a unitary operator, by Theorem 7.53. Thus, (3) implies (1).

We have shown (1) \Rightarrow (2) \Rightarrow (3) \Rightarrow (1), thus completing the proof. \square

6 Suppose T_1, T_2 are both normal operators on \mathbb{F}^3 with 2, 5, 7 as eigenvalues. Prove that there exists a unitary operator $S \in \mathcal{L}(\mathbb{F}^3)$ such that $T_1 = S^*T_2S$.

Solution:

Let e_1, e_2, e_3 be normalized eigenvectors of T_1 corresponding to eigenvalues 2, 5, 7; also let f_1, f_2, f_3 be normalized eigenvectors of T_2 corresponding to eigenvalues 2, 5, 7. As T_1 and T_2 are normal operators, these vectors are orthogonal to each other by Theorem 7.22. Thus, e_1, e_2, e_3 and f_1, f_2, f_3 are two orthonormal bases of \mathbb{F}^3 .

Define $S \in \mathcal{L}(\mathbb{F}^3)$ as

$$Se_k = f_k$$

for $k = 1, 2, 3$. This operator is unitary. First it is an isometry, as can be easily checked

$$\begin{aligned} \|Sv\|^2 &= \|a_1Se_1 + a_2Se_2 + a_3Se_3\|^2 \\ &= \|a_1f_1 + a_2f_2 + a_3f_3\|^2 \\ &= |a_1|^2 + |a_2|^2 + |a_3|^2 = \|v\|^2 \end{aligned}$$

for any $v = a_1e_1 + a_2e_2 + a_3e_3 \in \mathbb{F}^3$. Second, it is an invertible map, with S^{-1} defined via $S^{-1}f_k = e_k$ for $k = 1, 2, 3$. By Theorem 7.53, $S^* = S^{-1}$. Now we have:

$$\begin{aligned} T_1v &= T(a_1e_1 + a_2e_2 + a_3e_3) = a_1T_1e_1 + a_2T_1e_2 + a_3T_1e_3 \\ &= 2a_1e_1 + 5a_2e_2 + 7a_3e_3, \\ S^*T_2Sv &= S^*T_2(a_1f_1 + a_2f_2 + a_3f_3) = S^*(2a_1f_1 + 5a_2f_2 + 7a_3f_3) \\ &= 2a_1e_1 + 5a_2e_2 + 7a_3e_3. \end{aligned}$$

Hence, $T_1 = S^*T_2S$, as desired. \square

7 Give an example of two self-adjoint operators $T_1, T_2 \in \mathcal{L}(\mathbb{F}^4)$ such that the eigenvalues of both operators are 2, 5, 7 but there does not exist a unitary operator $S \in \mathcal{L}(\mathbb{F}^4)$ such that $T_1 = S^*T_2S$. Be sure to explain why there is no unitary operator with the required property.

Solution:

Let e_1, e_2, e_3, e_4 be a standard basis of \mathbb{F}^4 . Let T_1 be an operator such that $T_1e_1 = 2e_1$, $T_1e_2 = 5e_2$, $T_1e_3 = 5e_3$, $T_1e_4 = 7e_4$, and let T_2 be an operator such that $T_2e_1 = 5e_1$, $T_2e_2 = 2e_2$, $T_2e_3 = 7e_3$, $T_2e_4 = 2e_4$. These are operators diagonal with respect to an orthonormal basis, hence they are self-adjoint.

Suppose there is a unitary operator $S \in \mathcal{L}(\mathbb{F}^4)$ such that $T_1 = S^*T_2S$. For each vector in the basis we have

$$\begin{aligned} T_1e_j &= \lambda_j e_j \\ \|S^*T_2Se_j\| &= \|T_2Se_j\| = |\lambda_j| \end{aligned}$$

Let $T_2Se_j = \lambda_j f_j$, where $f_j \in \mathbb{F}^4$ and $\|f_j\| = 1$. Then we have $S^*f_j = e_j$, and acting on both sides by S we have $Se_j = f_j$. Therefore, f_j is an eigenvector of T_2 with an eigenvalue λ_j of T_1 .

Examine e_2 and e_3 . For them we get that f_2 and f_3 are eigenvectors of T_2 with eigenvalue 5. That implies $f_2 = f_3 = e_1$. But $f_2 = Se_2$ and $f_3 = Se_3$, and according to Theorem 7.53, Se_2 and Se_3 must be linearly independent, which is not the case here.

Thus, our assumption was wrong and there is no unitary operator S such that $T_1 = S^*T_2S$. \square

8 Prove or give a counterexample: If $S \in \mathcal{L}(V)$ and there exists an orthonormal basis e_1, \dots, e_n of V such that $\|Se_k\| = 1$ for each e_k , then S is a unitary operator.

Solution:

We can have S such that $Se_j = e_1$ for all e_j in the basis. Here $\|Se_j\| = 1$ for each e_j and S is not a unitary operator, because it is not invertible. \square

9 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Suppose every eigenvalue of T has absolute value 1 and $\|Tv\| \leq \|v\|$ for every $v \in V$. Prove that T is a unitary operator.

Solution:

First note that T is invertible. If it were not, then zero would be an eigenvalue of T , which cannot be, by condition of the problem.

By Shur's theorem (6.38), there is an orthonormal basis e_1, \dots, e_n , with respect to which T has an upper-triangular matrix:

$$\mathcal{M}(T) = \begin{pmatrix} \lambda_1 & a_{1,2} & \dots & a_{1,n} \\ 0 & \lambda_2 & \dots & a_{2,n} \\ \vdots & & \ddots & \vdots \\ 0 & \dots & 0 & \lambda_n \end{pmatrix},$$

where λ_j are eigenvalues of T , which are diagonal elements of this matrix by Theorem 5.41.

Consider T acting on some basis vector e_k :

$$Te_k = \lambda_k e_k + \sum_{j=1}^{k-1} a_{j,k} e_j$$

Because $\|Tv\| \leq \|v\|$ for every $v \in V$, we have:

$$\|Te_k\| \leq \|e_k\| = 1$$

At the same time:

$$\|Te_k\| = \sqrt{\left\| \lambda_k e_k + \sum_{j=1}^{k-1} a_{j,k} e_j \right\|^2} = \sqrt{|\lambda_k|^2 + \sum_{j=1}^{k-1} |a_{j,k}|^2} = \sqrt{1 + \sum_{j=1}^{k-1} |a_{j,k}|^2}$$

Thus, $\sqrt{1 + \sum_{j=1}^{k-1} |a_{j,k}|^2} \leq 1$, which is possible only if $\sum_{j=1}^{k-1} |a_{j,k}|^2 = 0$. This, in turn, implies that elements $a_{j,k} = 0$.

As it is true for any e_k , we conclude that the only non-zero matrix elements are diagonal elements. It means that $Te_k = \lambda_k e_k$, $|\lambda_k| = 1$ for every basis vector. Hence Te_1, Te_2, \dots, Te_n is an orthonormal basis of V , which by Theorem 7.53 implies that T is a unitary operator. \square

10 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is a self-adjoint operator such that $\|Tv\| \leq \|v\|$ for all $v \in V$.

(a) Show that $I - T^2$ is a positive operator.

(b) Show that $T + i\sqrt{I - T^2}$ is a unitary operator.

Solution:

(a) Let e_1, \dots, e_n be an orthonormal basis of V , with respect to which T is diagonalizable (see Spectral Theorem). Then for each vector in the basis, we have $Te_j = \lambda_j e_j$ with $|\lambda_j| \leq 1$ in order to satisfy property $\|Tv\| \leq \|v\|$ for all $v \in V$. For each e_j in the basis:

$$\langle (I - T^2)e_j, e_j \rangle = \langle (1 - \lambda_j^2)e_j, e_j \rangle = 1 - \lambda_j^2 \geq 0.$$

Hence, all diagonal entries of the matrix of $(I - T^2)$ with respect to basis e_1, \dots, e_n are nonnegative; Theorem 7.38 then implies that $(I - T^2)$ is a positive operator. \square

(b) Here we need to use a fact that an eigenvector of $(I - T^2)$ is also an eigenvector of $\sqrt{I - T^2}$. This was proven within the proof of Theorem 7.39.

Vectors e_j of the orthonormal basis from (a) are eigenvectors of $(I - T^2)$ with eigenvalues $1 - \lambda_j^2$. Hence, e_j 's are eigenvectors of $\sqrt{I - T^2}$ with eigenvalues $\sqrt{1 - \lambda_j^2}$'s.

We have

$$(T + i\sqrt{I - T^2})e_j = (\lambda_j + i\sqrt{1 - \lambda_j^2})e_j,$$

so e_j 's are eigenvectors of $T + i\sqrt{I - T^2}$ and their eigenvalues have an absolute value:

$$|\lambda_j + i\sqrt{1 - \lambda_j^2}| = \sqrt{\lambda_j^2 + 1 - \lambda_j^2} = 1.$$

By Theorem 7.55, $T + i\sqrt{I - T^2}$ is a unitary operator. \square

11 Suppose $S \in \mathcal{L}(V)$. Prove that S is a unitary operator if and only if

$$\{Sv : v \in V \text{ and } \|v\| \leq 1\} = \{v \in V : \|v\| \leq 1\}.$$

Solution:

Proof in the forward direction is straightforward. If S is unitary, then $\|Sv\| = \|v\|$, hence $\{Sv : v \in V \text{ and } \|v\| \leq 1\} \subseteq \{v \in V : \|v\| \leq 1\}$. Because S is surjective, it maps the entire subset of V in question (unit sphere) to itself, as desired.

Now suppose that $\{Sv : v \in V \text{ and } \|v\| \leq 1\} = \{v \in V : \|v\| \leq 1\}$ is true. Later we refer to this property as that S is an automorphism of a unit sphere of V .

First note that S is invertible, because if it were not, it would be not surjective, and hence would not be an automorphism of a unit sphere.

In order to show that S is unitary, suppose there is $S \in \mathcal{L}(V)$ which is not unitary and which satisfies the assumed property. Note, that $\|Sv\| \leq \|v\|$ for all v in the unit sphere. If there were such w in the unit sphere, for which $\|Sw\| > \|w\|$, then we can take $\alpha = 1/\|w\|$ and then we have $\|S(\alpha w)\| = \alpha\|Sw\| > \alpha\|w\| = 1$. This contradicts the assumption that S is an automorphism of a unit sphere.

Let $w = Sv$, so $v = S^{-1}w$. We can rewrite $\|Sv\| \leq \|v\|$ as $\|w\| \leq \|v\|$, which implies $\|S^{-1}w\| \geq \|w\|$. This property holds for every w in the unit sphere.

Consider v such that $\|v\| = 1$. Then $\|S^{-1}v\| \geq 1$. If $\|S^{-1}v\| > 1$, then this means that a vector $u \in V$ such that $Su = v$ is not an element of the unit sphere. That implies there is no w in the unit sphere such that $Sw = v$, so Sw is not in the unit sphere. That contradicts our assumption, hence we must have $\|S^{-1}v\| = \|v\|$ for v such that $\|v\| = 1$. Denoting $w = S^{-1}v$, we have $\|Sw\| = \|v\| = 1 = \|w\|$. Thus, $\|Sv\| = \|v\| = 1$ for any $v \in V$ such $\|v\| = 1$.

Now for the same vector v let, $u = \alpha v$, where $\alpha \in \mathbb{F}$. Then we have $\|Su\| = |\alpha|\|Sv\| = |\alpha| = \|u\|$. Because for any $u \in V$ we can set $\alpha = \|u\|$, that implies $\|Su\| = \|u\|$ for any $u \in V$, hence S is a unitary operator. \square

12 Prove or give a counterexample: If $S \in \mathcal{L}(V)$ is invertible and $\|S^{-1}v\| = \|Sv\|$ for every $v \in V$, then S is unitary.

Solution:

Let $V = \mathbb{R}^2$ and e_1, e_2 is a standard basis of V . Let S be an operator defined as:

$$Se_1 = \frac{1}{3}e_2, \quad Se_2 = 3e_1.$$

S is surjective, hence it is invertible. Applying S^{-1} on the both sides of the equations above, we have

$$\begin{aligned} S^{-1}Se_1 &= \frac{1}{3}S^{-1}e_2 \quad \Rightarrow \quad S^{-1}e_2 = 3e_1, \\ S^{-1}Se_2 &= 3S^{-1}e_1 \quad \Rightarrow \quad S^{-1}e_1 = \frac{1}{3}e_2. \end{aligned}$$

Hence, $S^{-1} = S$. This implies $\|S^{-1}v\| = \|Sv\|$ for every $v \in V$. We have $S \in \mathcal{L}(V)$, which is invertible and $\|S^{-1}v\| = \|Sv\|$ for every v , but S is not unitary, thus providing a counterexample. \square

13 Explain why the columns of a square matrix of complex numbers form an orthonormal list in \mathbb{C}^n if and only if the rows of the matrix form an orthonormal list in \mathbb{C}^n .

Solution:

Let A be a matrix and $S \in \mathcal{L}(\mathbb{C}^n)$ be an operator, whose matrix with respect to the standard basis is A . Rows of A form an orthonormal list in \mathbb{C}^n if and only if S is a unitary operator (Theorem 7.53). That also means S^* is a unitary operator, which is equivalent to the fact that rows of S^* form an orthonormal list in \mathbb{C}^n (Theorem 7.53). Matrix of S^* is a conjugate transpose of the matrix of S , A^* . Thus, complex conjugate columns of A form a linearly independent list in \mathbb{C}^n . Complex conjugation does not affect linear independence. Thus, columns of A are linearly independent. \square

14 Suppose $v \in V$ with $\|v\| = 1$ and $b \in \mathbb{F}$. Also suppose $\dim V \geq 2$. Prove that there exists a unitary operator $S \in \mathcal{L}(V)$ such that $\langle Sv, v \rangle = b$ if and only if $|b| \leq 1$.

Solution:

First suppose that there exists a unitary operator S such that $\langle Sv, v \rangle = b$. Using Cauchy-Schwarz inequality (6.14), we have

$$|b| = |\langle Sv, v \rangle| \leq \|Sv\| \|v\| = 1,$$

as desired.

Now suppose that $|b| \leq 1$. Let $e_1 = v$, and extend this vector to an orthonormal basis e_1, \dots, e_n of V ($n \geq 2$). Let S be an operator such that $Se_1 = be_1 + \sqrt{1 - |b|^2}e_2$, $Se_2 = -\sqrt{1 - |b|^2}e_1 + be_2$, $Se_k = e_k$ for $k \geq 3$. Note that

$$\langle Sv, v \rangle = \langle Se_1, e_1 \rangle = b.$$

We need to show that S is a unitary operator. We will show it by proving that Se_1, \dots, Se_n is an orthonormal list in V . Se_3, \dots, Se_n is just e_3, \dots, e_n , thus this list is orthonormal. Se_1 and Se_2 are linear combinations of e_1 and e_2 , hence these two vectors are orthogonal to each vector in e_3, \dots, e_n . These are also normal:

$$\begin{aligned} \|Se_1\|^2 &= \|be_1 + \sqrt{1 - |b|^2}e_2\|^2 = |b|^2 + 1 - |b|^2 = 1, \\ \|Se_2\|^2 &= \|- \sqrt{1 - |b|^2}e_1 + be_2\|^2 = 1 - |b|^2 + |b|^2 = 1, \end{aligned}$$

and orthogonal:

$$\langle Se_1, Se_2 \rangle = \langle be_1 + \sqrt{1 - |b|^2}e_2, -\sqrt{1 - |b|^2}e_1 + be_2 \rangle = -b\sqrt{1 - |b|^2} + b\sqrt{1 - |b|^2} = 0.$$

Thus, Se_1, \dots, Se_n is an orthonormal list in V , therefore S is a unitary operator, by Theorem 7.49. \square

15 Suppose T is a unitary operator on V such that $T - I$ is invertible.

- (a) Prove that $(T + I)(T - I)^{-1}$ is a skew operator.
- (b) Prove that if $\mathbb{F} = \mathbb{C}$, then $i(T + I)(T - I)^{-1}$ is a self-adjoint operator.

Solution:

(a) Using property 7.5 and theorem 7.53 we have:

$$\begin{aligned} [(T + I)(T - I)^{-1}]^* &= [(T - I)^{-1}]^*(T + I)^* = [(T - I)^*]^{-1}(T^* + I) \\ &= (T^* - I)^{-1}(T^* + I) = (T^* - TT^*)^{-1}(T^* + T^*T) \\ &= (I - T)^{-1}(T^*)^{-1}T^*(I + T) \\ &= -(T - I)^{-1}(T + I) = -(T + I)(T - I)^{-1} \end{aligned}$$

In the last equality we use commutativity of $(T + I)$ and $(T - I)^{-1}$. This can be easily shown starting from the commutativity of $T + I$ and $T - I$, which follows from property 5.17.

$$\begin{aligned} (T - I)^{-1}(T + I) &= (T - I)^{-1}(T + I)(T - I)(T - I)^{-1} \\ &= (T - I)^{-1}(T - I)(T + I)(T - I)^{-1} \\ &= (T + I)(T - I)^{-1}. \end{aligned}$$

Thus, $(T + I)(T - I)^{-1}$ is a skew operator. \square

(b) Here we can use the result of part (a):

$$[i(T + I)(T - I)^{-1}]^* = -i[(T + I)(T - I)^{-1}]^* = i(T + I)(T - I)^{-1}. \quad \square$$

16 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is self-adjoint. Prove that $(T + iI)(T - iI)^{-1}$ is a unitary operator and 1 is not an eigenvalue of this operator.

Solution:

First, let us find the adjoint of $(T + iI)(T - iI)^{-1}$.

$$\begin{aligned}
[(T + iI)(T - iI)^{-1}]^* &= [(T - iI)^{-1}]^*(T + iI)^* \\
&= (T^* + iI)^{-1}(T^* - iI) \\
&= (T + iI)^{-1}(T - iI),
\end{aligned}$$

where we used properties 7.5d in the first equality, 7.5b, f in the second equality and the fact that T is self-adjoint in the last. Now we have

$$\begin{aligned}
(T + iI)(T - iI)^{-1}[(T + iI)(T - iI)^{-1}]^* &= (T + iI)(T - iI)^{-1}(T + iI)^{-1}(T - iI) \\
&= (T - iI)^{-1}(T + iI)(T + iI)^{-1}(T - iI) \\
&= (T - iI)^{-1}(T - iI) \\
&= I,
\end{aligned}$$

where commutativity of $(T + iI)$ and $(T - iI)^{-1}$ can be shown the same way as in *Problem 7D.15*. Similarly:

$$\begin{aligned}
[(T + iI)(T - iI)^{-1}]^*(T + iI)(T - iI)^{-1} &= (T + iI)^{-1}(T - iI)(T + iI)(T - iI)^{-1} \\
&= (T + iI)^{-1}(T - iI)(T - iI)^{-1}(T + iI) \\
&= (T + iI)^{-1}(T + iI) \\
&= I.
\end{aligned}$$

Theorem 7.53 then implies that $(T + iI)(T - iI)^{-1}$ is a unitary operator.

Now we show that it cannot have 1 as an eigenvalue. Because T is self-adjoint, Spectral Theorem implies that there exist an orthonormal basis e_1, \dots, e_n of V consisting of eigenvectors of T . Denote these eigenvalues by $\lambda_1, \dots, \lambda_n$. Note that these vectors are also eigenvectors of $T + iI$ and $T - iI$:

$$\begin{aligned}
(T + iI)e_j &= Te_j + ie_j = (\lambda_j + i)e_j, \\
(T - iI)e_j &= Te_j - ie_j = (\lambda_j - i)e_j,
\end{aligned}$$

Using result of *Problem 5D.7*, we have that e_j 's are also eigenvectors of $(T - iI)^{-1}$ with eigenvalues $1/(\lambda_j - i)$. Then, these are also eigenvectors of $(T + iI)(T - iI)^{-1}$ as well:

$$(T + iI)(T - iI)^{-1}e_j = (T + iI)\left(\frac{1}{\lambda_j - i}e_j\right) = \frac{\lambda_j + i}{\lambda_j - i}e_j.$$

Set of $(\lambda_j + i)/(\lambda_j - i)$ is a complete set of eigenvalues of $(T + iI)(T - iI)^{-1}$. Existence of any other eigenvalue requires an eigenvector linearly independent of e_1, \dots, e_n (Theorem 5.11), which is not possible because it is a basis of V .

Suppose for some λ_j we have $(\lambda_j + i)/(\lambda_j - i) = 1$. Multiplying both sides of the equation by $\lambda_j - i$, we have

$$\lambda_j + i = \lambda_j - i \quad \Rightarrow \quad i = -i,$$

which is not true. Thus, $(T + iI)(T - iI)^{-1}$ cannot have 1 as an eigenvalue, which completes the proof. \square

17 Explain why the characterization of unitary matrices given by 7.57 hold.

Solution:

Think of a unitary matrix as an operator on \mathbb{C}^n (with standard basis). Then 7.57a corresponds to 7.53a, 7.57b corresponds to 7.53e, 7.57c corresponds to the definition of a unitary operator and 7.57d corresponds to 7.53b.

18 A square matrix A is called *symmetric* if it equals its transpose. Prove that if A is a symmetric matrix with real entries, then there exists a unitary matrix Q with real entries such that Q^*AQ is a diagonal matrix.

Solution:

$A \in \mathbb{R}^{n,n}$, $A^t = A$. Let $T \in \mathcal{L}(\mathbb{R})$ be such that its matrix with respect to the standard basis e_1, \dots, e_n equals A . Then $\mathcal{M}(T^*) = A^t = A = \mathcal{M}(T)$, hence T is self-adjoint. By the Real Spectral Theorem (7.29), there exists an orthonormal basis f_1, \dots, f_n of V , with respect to which the matrix of T is diagonal; denote it by B . Using change-of-basis formula (3.84), we have $B = Q^{-1}AQ$, where $Q = \mathcal{M}(I, (f_1, \dots, f_n), (e_1, \dots, e_n))$.

Note, that $Q^* = \mathcal{M}(I, (e_1, \dots, e_n), (f_1, \dots, f_n))$, thus $Q^*Q = \mathcal{M}(I, (e_1, \dots, e_n))$ and $Q^*Q = \mathcal{M}(I, (f_1, \dots, f_n))$. Using equivalence of 7.58d and a, we have that Q is a unitary matrix. Thinking now of Q as an operator on \mathbb{R}^n , we can use 7.53c to get $Q^{-1} = Q^*$, which gives Q^*AQ is a diagonal matrix. \square

19 Suppose n is a positive integer. For this exercise, we adopt the notation that a typical element z of \mathbb{C}^n is denoted by $z = (z_0, z_1, \dots, z_{n-1})$. Define linear functionals $\omega_0, \omega_1, \dots, \omega_{n-1}$ on \mathbb{C}^n by

$$\omega_j(z_0, z_1, \dots, z_{n-1}) = \frac{1}{\sqrt{n}} \sum_{m=0}^{n-1} z_m e^{-2\pi i j m / n}.$$

The *discrete Fourier transform* is the operator $\mathcal{F} : \mathbb{C}^n \rightarrow \mathbb{C}^n$ defined by

$$\mathcal{F}z = (\omega_0(z), \omega_1(z), \dots, \omega_{n-1}(z)).$$

(a) Show that \mathcal{F} is a unitary operator on \mathbb{C}^n .

(b) Show that if $(z_0, \dots, z_{n-1}) \in \mathbb{C}^n$ and z_n is defined to equal z_0 , then

$$\mathcal{F}^{-1}(z_0, z_1, \dots, z_{n-1}) = \mathcal{F}(z_n, z_{n-1}, \dots, z_1).$$

(c) Show that $\mathcal{F}^4 = I$.

Solution:

(a) Let evaluate matrix of \mathcal{F} with respect to the standard basis of \mathbb{C}^n . Using definition of the discrete Fourier transform and ω_j 's we have:

$$\mathcal{M}(\mathcal{F}) = \frac{1}{\sqrt{n}} \begin{pmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & \exp(-2\pi i \frac{1}{n}) & \exp(-2\pi i \frac{2}{n}) & \cdots & \exp(-2\pi i \frac{n-1}{n}) \\ 1 & \exp(-2\pi i \frac{2}{n}) & \exp(-2\pi i \frac{4}{n}) & \cdots & \exp(-2\pi i \frac{2(n-1)}{n}) \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \exp(-2\pi i \frac{n-1}{n}) & \exp(-2\pi i \frac{2(n-1)}{n}) & \cdots & \exp(-2\pi i \frac{(n-1)^2}{n}) \end{pmatrix}$$

Now we can easily show that rows of this matrix form an orthonormal basis. First,

$$\begin{aligned} \langle \mathcal{M}_{k,\cdot}, \mathcal{M}_{k,\cdot} \rangle &= \frac{1}{n} \left(1^2 + |\exp(-2\pi i \frac{k}{n})|^2 + |\exp(-2\pi i \frac{2k}{n})|^2 + \dots \right. \\ &\quad \left. + |\exp(-2\pi i \frac{k(n-1)}{n})|^2 \right) = \frac{1}{n} \cdot n = 1. \end{aligned}$$

Second,

$$\begin{aligned} \langle \mathcal{M}_{k,\cdot}, \mathcal{M}_{l,\cdot} \rangle &= \frac{1}{n} \left(1 + \exp(-2\pi i \frac{k-l}{n}) + \exp(-2\pi i \frac{2(k-l)}{n}) + \dots \right. \\ &\quad \left. + \exp(-2\pi i \frac{(n-1)(k-l)}{n}) \right) \\ &= \frac{1}{n} \frac{\exp[-2\pi i(k-l)] - 1}{\exp[-2\pi i(k-l)/n] - 1} = 0, \end{aligned}$$

where we used formula for a sum of geometric progression in the second equality. Hence, by Theorem 7.53, \mathcal{F} is a unitary operator. \square

(b) Using 7.53c, we have

$$\mathcal{F}^{-1}z = \mathcal{F}^*z = (\omega_0^*(z), \omega_1^*(z), \dots, \omega_{n-1}^*(z)),$$

where

$$\omega_j^*(z) = \frac{1}{\sqrt{n}} \sum_{m=0}^{n-1} z_m e^{2\pi i j m/n}.$$

This formula can be obtained by taking a complex conjugate transpose of the matrix of \mathcal{F} . First, note that $\omega_0^* = \omega_0$. For others, we have

$$\begin{aligned} \omega_j^*(z_0, z_1, \dots, z_{n-1}) &= \frac{1}{\sqrt{n}} \sum_{m=0}^{n-1} z_m e^{2\pi i j m/n} = \frac{1}{\sqrt{n}} \sum_{m=0}^{n-1} z_m e^{2\pi i j m/n - 2\pi i} \\ &= \frac{1}{\sqrt{n}} \sum_{m=0}^{n-1} z_m e^{-2\pi i j (n-m)/n} \\ &= \frac{1}{\sqrt{n}} \sum_{l=0}^{n-1} z_{(n-l)} e^{-2\pi i j (n-m)/n} \\ &= \omega_j(z_n, z_{n-1}, \dots, z_1), \end{aligned}$$

where we set $z_n = z_0$. That proves the desired result. \square

(c) Let $z \in \mathbb{C}^n$, $z = (z_0, z_1, \dots, z_{n-1})$. Then

$$\begin{aligned} \mathcal{F}^4 z &= \mathcal{F}^3 \mathcal{F}^{-1}(z_0, z_{n-1}, \dots, z_1) = \mathcal{F}^2(z_0, z_{n-1}, \dots, z_1) \\ &= \mathcal{F} \mathcal{F}^{-1}(z_0, z_1, \dots, z_{n-1}) = z. \end{aligned}$$

Thus, $\mathcal{F}^4 = I$. \square

20 Suppose A is a square matrix with linearly independent columns. Prove that there exists unique matrices R and Q such that R is lower triangular with only positive numbers on its diagonal, Q is unitary, and $A = RQ$.

Solution:

First, consider transpose of A . Denote number of columns of A as n . Because A is a square matrix with linearly independent columns, its row rank equals n (by Theorem 3.57). Then column rank of A^t equals row rank of A , that is n . Thus, A^t is a matrix with linearly independent columns. Applying Theorem 7.58 to A^t , we have $A^t = ST$, where S is a unitary matrix and T is upper-triangular. Then

$$A = (A^t)^t = (ST)^t = T^t S^t.$$

Here T^t is lower triangular matrix; let $R = T^t$. S is unitary, that is its columns form an orthonormal list in \mathbb{F}^n , hence rows of S^t form an orthonormal list in \mathbb{F}^n . By Theorem 7.57, S^t is a unitary matrix; let $Q = S^t$. Thus, we have

$$A = RQ,$$

where R is a lower triangular and Q is a unitary matrix, as desired. \square

7E Singular Value Decomposition

1 Suppose $T \in \mathcal{L}(V, W)$. Show that $T = 0$ if and only if all singular values of T are 0.

Solution:

First suppose that $T = 0$. Then for every $v \in V$, $T^*Tv = T^*(0) = 0$. Thus, the only eigenvalue of T^*T is 0, which means all singular values of T are 0.

Now suppose that all singular values of T are zero. That means the operator T^*T has only 0 as eigenvalue. Because T^*T is a positive operator (Theorem 7.64), it is self-adjoint (Theorem 7.38b). By the Spectral Theorem, T^*T is diagonalizable operator (Theorems 7.29 and 7.31), which implies $V = E(0, T^*T)$ (Theorem 5.55). Thus, $\text{null } T^*T = V$. Theorem 7.64b then implies $\text{null } T = \text{null } T^*T = V$, hence $T = 0$. \square

2 Suppose $T \in \mathcal{L}(V, W)$ and $s > 0$. Prove that s is a singular value of T if and only if there exist nonzero vectors $v \in V$ and $w \in W$ such that

$$Tv = sw \quad \text{and} \quad T^*w = sv.$$

Solution:

First suppose there exist such vectors v and w . Then we have

$$T^*Tv = T^*(sw) = sT^*w = s^2v.$$

Thus, s^2 is an eigenvalue of T^*T , and hence s is a singular value of T .

Now suppose s is a singular value of T . Let $v \in V$, $\|v\| = 1$ be an eigenvector of T^*T corresponding to the eigenvalue s^2 of T^*T : $T^*Tv = s^2v$. Then we have

$$\begin{aligned} \langle T^*Tv, v \rangle &= s^2, \\ \langle T^*Tv, v \rangle &= \langle Tv, Tv \rangle = \|Tv\|. \end{aligned}$$

Let $w = Tv/\|Tv\| = \frac{1}{s}Tv$ ($w \in W$). We have

$$T^*w = T^*\left(\frac{1}{s}Tv\right) = \frac{1}{s}T^*Tv = sv.$$

Thus, there exist $v \in V$ and $w \in W$ such that $Tv = sw$ and $T^*w = sv$. \square

3 Give an example of $T \in \mathcal{L}(\mathbb{C}^2)$ such that 0 is the only eigenvalue of T and the singular values of T are 5, 0.

Solution:

Let $T \in \mathcal{L}(\mathbb{C}^2)$ be an operator with the following matrix with respect to the standard basis of \mathbb{C}^2 :

$$\mathcal{M}(T) = \begin{pmatrix} 0 & 5 \\ 0 & 0 \end{pmatrix}.$$

Matrix of T is upper-triangular, hence diagonal elements are eigenvalues of T (Theorem 5.41). Thus, T is indeed such that 0 is its only eigenvalue.

The matrix of T^* is a complex conjugate transpose of T (Theorem 7.9). Applying matrix multiplication, we arrive at the matrix of T^*T .

$$\mathcal{M}(T^*T) = \mathcal{M}(T^*) \cdot \mathcal{M}(T) = \begin{pmatrix} 0 & 0 \\ 5 & 0 \end{pmatrix} \cdot \begin{pmatrix} 0 & 5 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 25 \end{pmatrix}.$$

Thus, T^*T is diagonalizable with respect to the standard basis of \mathbb{C}^2 with diagonal elements equal 0 and 25, which are eigenvalues of T^*T . This implies that the singular values of T are 5, 0, as desired. \square

4 Suppose that $T \in \mathcal{L}(V, W)$, s_1 is the largest singular value of T , and s_n is the smallest singular value of T . Prove that

$$\{\|Tv\| : v \in V \text{ and } \|v\| = 1\} = [s_n, s_1].$$

Solution:

Let e_1, \dots, e_n be an orthonormal basis of V which diagonalizes T^*T . Eigenvalues of T^*T are then s_1^2, \dots, s_n^2 . Without loss of generality, suppose eigenvectors e_1, \dots, e_n are in decreasing order of eigenvalues. Then for any $v \in V$, $v = a_1e_1 + \dots + a_ne_n$, such that $\|v\| = 1$ we have

$$\begin{aligned} \|Tv\|^2 &= \langle Tv, Tv \rangle = \langle T^*Tv, v \rangle \\ &= \langle s_1^2a_1e_1 + \dots + s_n^2a_ne_n, a_1e_1 + \dots + a_ne_n \rangle \\ &= s_1^2|a_1|^2 + \dots + s_n^2|a_n|^2. \end{aligned}$$

This implies

$$\begin{aligned} \|Tv\|^2 &= s_1^2|a_1|^2 + \dots + s_n^2|a_n|^2 \leq s_1^2(|a_1|^2 + \dots + |a_n|^2) = s_1^2 \\ \|Tv\|^2 &= s_1^2|a_1|^2 + \dots + s_n^2|a_n|^2 \geq s_n^2(|a_1|^2 + \dots + |a_n|^2) = s_n^2. \end{aligned}$$

Thus, $s_n \leq \|Tv\| \leq s_1$, which means $\{\|Tv\| : v \in V \text{ and } \|v\| = 1\} \subseteq [s_n, s_1]$.

We also need to show that there are no holes in the interval $[s_n, s_1]$. Take a linear combination $v = e_1 \cos \phi + e_n \sin \phi$, where ϕ is a real-valued parameter in the interval $[0, 1]$. Here we have

$$\|Tv\| = \sqrt{s_1^2 \cos^2 \phi + s_n^2 \sin^2 \phi}.$$

Thus, for such v , $\|Tv\|$ is a continuous function. Intermediate value theorem then implies that there exist $\phi \in [0, 1]$ such that $\|Tv\| = s$ for any $s \in [s_n, s_1]$, which proves the desired result. \square

5 Suppose $T \in \mathcal{L}(\mathbb{C}^2)$ is defined by $T(x, y) = (-4y, x)$. Find the singular values of T .

Solution:

With respect to the standard basis of \mathbb{C}^2 , matrix of T is

$$\mathcal{M}(T) = \begin{pmatrix} 0 & -4 \\ 1 & 0 \end{pmatrix}.$$

Taking its conjugate transpose, we arrive at the matrix of T^* :

$$\mathcal{M}(T^*) = \begin{pmatrix} 0 & 1 \\ -4 & 0 \end{pmatrix}.$$

Now using matrix multiplication, we have the matrix of T^*T :

$$\mathcal{M}(T) = \mathcal{M}(T^*)\mathcal{M}(T) = \begin{pmatrix} 0 & 1 \\ -4 & 0 \end{pmatrix} \cdot \begin{pmatrix} 0 & -4 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 16 \end{pmatrix}.$$

Thus, T^*T is diagonalizable with respect to the standard basis. From the matrix of T^*T we have its eigenvalues (1 and 16). Taking square root of them, we find that the singular values of T are 4, 1. \square

6 Find the singular values of the differentiation operator $D \in \mathcal{L}(\mathcal{P}_2(\mathbb{R}))$ defined by $Dp = p'$, where the inner product on $\mathcal{P}_2(\mathbb{R})$ is as in Example 6.34.

Solution:

We will take the orthonormal basis of $\mathcal{P}_2(\mathbb{R})$ found in Example 6.34: $\sqrt{1/2}$, $\sqrt{3/2}x$, $\sqrt{45/8}(x^2 - 1/3)$. D acts on this basis as following

$$De_1 = 0$$

$$De_2 = \sqrt{3/2} = \sqrt{3}e_1$$

$$De_3 = 2\sqrt{45/8}x = \sqrt{15}e_2.$$

Thus, matrices of D and D^* with respect to the chosen basis are

$$\mathcal{M}(D) = \begin{pmatrix} 0 & \sqrt{3} & 0 \\ 0 & 0 & \sqrt{15} \\ 0 & 0 & 0 \end{pmatrix}, \quad \mathcal{M}(D^*) = \begin{pmatrix} 0 & 0 & 0 \\ \sqrt{3} & 0 & 0 \\ 0 & \sqrt{15} & 0 \end{pmatrix}.$$

Then, for D^*D we have

$$\begin{aligned} \mathcal{M}(D^*D) &= \mathcal{M}(D^*) \cdot \mathcal{M}(D) \\ &= \begin{pmatrix} 0 & 0 & 0 \\ \sqrt{3} & 0 & 0 \\ 0 & \sqrt{15} & 0 \end{pmatrix} \cdot \begin{pmatrix} 0 & \sqrt{3} & 0 \\ 0 & 0 & \sqrt{15} \\ 0 & 0 & 0 \end{pmatrix} \\ &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 15 \end{pmatrix}. \end{aligned}$$

Hence, eigenvalues of D^*D are 0, 3 and 15. This implies the singular values of D are $\sqrt{15}$, $\sqrt{3}$, 0. \square

7 Suppose that $T \in \mathcal{L}(V)$ is self-adjoint or that $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is normal. Let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of T , each included in this list as many times as the dimension of the corresponding eigenspace. Show that the singular values of T are $|\lambda_1|, \dots, |\lambda_n|$, after these numbers have been sorted into decreasing order.

Solution:

By the Spectral Theorem, there exists an orthonormal basis of V such that T is diagonalizable with respect to it; diagonal entries of A (matrix of T) are eigenvalues $\lambda_1, \dots, \lambda_n$ of T . Matrix of T^* is A^* , also a diagonal matrix, but with diagonal entries $\lambda_1^*, \dots, \lambda_n^*$.

Matrix of T^*T is thus also diagonal, with $|\lambda_1|^2, \dots, |\lambda_n|^2$ on the diagonal. Hence, these numbers are its eigenvalues. Then, by definition, singular values of T are $|\lambda_1|, \dots, |\lambda_n|$, when sorted in the decreasing order. \square

8 Suppose $T \in \mathcal{L}(V, W)$. Suppose $s_1 \geq s_2 \geq \dots \geq s_m > 0$ and e_1, \dots, e_m is an orthonormal list in V and f_1, \dots, f_m is an orthonormal list in W such that

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_m \langle v, e_m \rangle f_m$$

for every $v \in V$.

(a) Prove that f_1, \dots, f_m is an orthonormal basis of range T .

- (b) Prove that e_1, \dots, e_m is an orthonormal basis of $(\text{null } T)^\perp$.
- (c) Prove that s_1, \dots, s_m are the positive singular values of T .
- (d) Prove that if $k \in \{1, \dots, m\}$, then e_k is an eigenvector of T^*T with corresponding eigenvalue s_k^2 .
- (e) Prove that

$$TT^*w = s_1^2 \langle w, f_1 \rangle f_1 + \dots + s_m^2 \langle w, f_m \rangle f_m$$

for all $w \in W$.

Solution:

(a) By definition of f_1, \dots, f_m given above, this list spans the set of all Tv , that is $\text{range } T$. It is an orthonormal list, hence it is linearly independent. By definition, it is a basis of $\text{range } T$. Hence, it is an orthonormal basis of $\text{range } T$.

(b) Suppose $v \in \text{null } T$. As s_1, \dots, s_m are all nonzero, we must have $\langle v, e_j \rangle = 0$ for each $k = 1, \dots, m$. Therefore, $\text{span } e_1, \dots, e_m \subseteq (\text{null } T)^\perp$. Combining Theorem 6.51 and the Fundamental Theorem of Linear Maps, we have $\dim(\text{null } T)^\perp = m$, where we also use the result of part (a). This implies e_1, \dots, e_m is a list of length equal to the dimension of the vector space, hence it is a (orthonormal) basis of $(\text{null } T)^\perp$.

(c, d) Following the proof of Theorem 7.75, we have an expression for adjoint T^* :

$$T^*w = s_1 \langle w, f_1 \rangle e_1 + \dots + s_m \langle w, f_m \rangle e_m.$$

Now for T^*T we have:

$$\begin{aligned} T^*Te_j &= T^*(s_1 \langle e_j, e_1 \rangle f_1 + \dots + s_m \langle e_j, e_m \rangle f_m) \\ &= T^*(s_j f_j) = s_j T^*f_j \\ &= s_j^2 e_j, \end{aligned}$$

where e_j is one of the basis vectors e_1, \dots, e_m . This implies s_1^2, \dots, s_m^2 are eigenvalues of T^*T repeated as many times the dimension of a corresponding eigenspace. Then, s_1, \dots, s_m are singular values of T by definition.

(e) For each $w \in W$ we have

$$\begin{aligned} TT^*w &= T(s_1 \langle w, f_1 \rangle e_1 + \dots + s_m \langle w, f_m \rangle e_m) \\ &= s_1 \langle w, f_1 \rangle Te_1 + \dots + s_m \langle w, f_m \rangle Te_m \\ &= s_1 \langle w, f_1 \rangle s_1 f_1 + \dots + s_m \langle w, f_m \rangle s_m f_m \\ &= s_1^2 \langle w, f_1 \rangle f_1 + \dots + s_m^2 \langle w, f_m \rangle f_m, \end{aligned}$$

as desired. \square

9 Suppose $T \in \mathcal{L}(V, W)$. Show that T and T^* have the same positive singular values.

Solution:

Suppose s_1, \dots, s_m are singular values of T . Use the corollary of singular value decomposition (7.75) and insert T^* in place of T in the *Problem 7E.8*. The result (c) of the previous exercise thus shows that s_1, \dots, s_m are also the singular values of T^* . \square

10 Suppose $T \in \mathcal{L}(V, W)$ has singular values s_1, \dots, s_n . Prove that if T is an invertible linear map, then T^{-1} has singular values

$$\frac{1}{s_n}, \dots, \frac{1}{s_1}.$$

Solution: If T is an invertible linear map, then T^* is also invertible and $(T^{-1})^* = (T^*)^{-1}$. Therefore

$$(T^{-1})^* T^{-1} = (T^*)^{-1} T^{-1} = (TT^*)^{-1}.$$

TT^* is a positive operator on W (see Theorem 7.64). That implies TT^* is diagonalizable with respect to some orthonormal basis of W . Note that the diagonal elements are squares of the singular values of T^* , which by the result of the previous exercise are the same as singular values of T .

Now the result of *Problem 5D.7* implies that the eigenvalues of $(TT^*)^{-1}$ are $1/s_1^2, \dots, 1/s_n^2$. That in turn means the singular values of T^{-1} are $1/s_n, \dots, 1/s_1$, as desired. \square

11 Suppose that $T \in \mathcal{L}(V, W)$ and v_1, \dots, v_n is an orthonormal basis of V . Let s_1, \dots, s_n denote the singular values of T .

(a) Prove that $\|Tv_1\|^2 + \dots + \|Tv_n\|^2 = s_1^2 + \dots + s_n^2$.

(b) Prove that if $W = V$ and T is a positive operator, then

$$\langle Tv_1, v_1 \rangle + \dots + \langle Tv_n, v_n \rangle = s_1 + \dots + s_n.$$

Solution:

(a) Because singular values are in the decreasing order, we can assume first m of them are nonzero. For s_1, \dots, s_m we can use the singular value decomposition (7.70): there exist orthonormal lists e_1, \dots, e_m and f_1, \dots, f_m in V and W that provide SVD. Then

$$\|Te_j\|^2 = s_j^2 \langle e_j, e_j \rangle^2 \|f_j\|^2 = s_j^2,$$

for $j = 1, \dots, m$. Using Gram-Schmidt procedure (6.32), we can extend e_1, \dots, e_m to an orthonormal basis and assign singular values s_{m+1}, \dots, s_n , which equal zero, to e_{m+1}, \dots, e_n .

Note that e_{m+1}, \dots, e_n spans $\text{null } T$ (use SVD), hence

$$\|Te_k\|^2 = 0 = s_k^2,$$

for $k = m+1, \dots, n$.

Now we have

$$\|Te_1\|^2 + \dots + \|Te_n\|^2 = s_1^2 + \dots + s_n^2.$$

In *Problem 7A.5* we have shown that the left hand side of the equation above does not depend on the chosen orthonormal basis. Hence we can take any orthonormal basis v_1, \dots, v_n of V , proving the desired result. \square

(b) T is a positive operator, hence there exists $R \in \mathcal{L}(V)$ such that $T = R^*R$ (7.38). Note that singular values coincide with eigenvalues of T , when arranged in the decreasing order. It can be shown by applying spectral theorem to T producing eigenvalues $\lambda_1, \dots, \lambda_n$ (all nonnegative) of T , and then using the fact that T is self-adjoint. Thus, $T^*T = T$ has eigenvalues $\lambda_1^2, \dots, \lambda_n^2$, which implies $\lambda_1, \dots, \lambda_n$ are singular values of T .

This means, the singular values of R are $\sqrt{s_1}, \dots, \sqrt{s_n}$. Now use the result of (a) and Theorem 7.38e (R is self-adjoint) to get the desired result:

$$\begin{aligned} \langle Tv_1, v_1 \rangle + \dots + \langle Tv_n, v_n \rangle &= \langle Rv_1, Rv_1 \rangle + \dots + \langle Rv_n, Rv_n \rangle \\ &= \|Rv_1\|^2 + \dots + \|Rv_n\|^2 \\ &= s_1 + \dots + s_n. \quad \square \end{aligned}$$

12 (a) Give an example of a finite-dimensional vector space and an operator T on it such that the singular values of T^2 do not equal the squares of the singular values of T .

(b) Suppose $T \in \mathcal{L}(V)$ is normal. Prove that the singular values of T^2 equal the squares of the singular values of T .

Solution:

(a) Take \mathbb{R}^2 as a finite-dimensional vector space and take the operator T , given by the matrix with respect to the standard basis:

$$\mathcal{M}(T) = \begin{pmatrix} 1 & 4 \\ -2 & 2 \end{pmatrix}.$$

First, we calculate singular values of T . Matrix of T^*T with respect to the standard basis is

$$\mathcal{M}(T^*T) = \begin{pmatrix} 1 & -2 \\ 4 & 2 \end{pmatrix} \cdot \begin{pmatrix} 1 & 4 \\ -2 & 2 \end{pmatrix} = \begin{pmatrix} 5 & 0 \\ 0 & 20 \end{pmatrix}.$$

Thus, the singular values of T are $2\sqrt{5}, \sqrt{5}$.

Now, the matrix of T^2 is

$$\mathcal{M}(T^2) = \begin{pmatrix} 1 & 4 \\ -2 & 2 \end{pmatrix}^2 = \begin{pmatrix} -7 & 12 \\ -6 & -4 \end{pmatrix}.$$

Now, for $(T^2)^*T^2$ we have

$$\mathcal{M}((T^2)^*T^2) = \begin{pmatrix} -7 & -6 \\ 12 & -4 \end{pmatrix} \cdot \begin{pmatrix} -7 & 12 \\ -6 & -4 \end{pmatrix} = \begin{pmatrix} 85 & -60 \\ -60 & 160 \end{pmatrix}.$$

Eigenvalues of $(T^2)^*T^2$ are given by the solution to a system of equations:

$$\begin{cases} 85x - 60y = \lambda x, \\ -60x + 160y = \lambda y. \end{cases}$$

Expressing y with the first equation as $y = (85 - \lambda)x/60$ and inserting it into the second, we get

$$-60x + (160 - \lambda)(85 - \lambda)x/60 = 0.$$

We can divide by $x \neq 0$ (because $(0, 1)$ is not an eigenvector) and multiply by 60 to get equation on λ .

$$\lambda^2 - 245\lambda + 13540 = 0. \quad (7.12)$$

If singular values of T^2 were the squares of singular values of T , then 20^2 and 5^2 would be solutions to 7.12. Plugging them into it we get:

$$\begin{aligned} 25^2 - 245 \cdot 25 + 13540 &= 8040, \\ 400^2 - 245 \cdot 400 + 13540 &= 75540. \end{aligned}$$

Thus, the operator T given above provides the sought example.

(b) Let s_1^2, \dots, s_n^2 be the eigenvalues of T^*T with corresponding orthonormal eigenvectors e_1, \dots, e_n (provided by Theorem 7.38 b and the Spectral Theorem).

By the definition of the normal operator, T commutes with T^* . Hence we have

$$(T^2)^*T^2 = T^*T^*TT = (T^*T)(T^*T).$$

For each e_j ($j = 1, \dots, n$) we then have

$$(T^2)^*T^2e_j = (T^*T)(T^*T)e_j = s_j^4e_j.$$

That implies the singular values of T^2 are s_1^2, \dots, s_n^2 , that is, the squares of the singular values of T . \square

13 Suppose $T_1, T_2 \in \mathcal{L}(V)$. Prove that T_1 and T_2 have the same singular values if and only if there exist unitary operators $S_1, S_2 \in \mathcal{L}(V)$ such that $T_1 = S_1T_2S_2$.

Solution:

First, suppose there exist unitary operators $S_1, S_2 \in \mathcal{L}(V)$ such that $T_1 = S_1T_2S_2$. Then $T_1^* = S_2^*T_2^*S_1^*$ and thus

$$T_1^*T_1 = S_2^*T_2^*S_1^*S_1T_2S_2 = S_2^*T_2^*T_2S_2,$$

where we used property 7.53b of unitary operators. Now let $\lambda \in \mathbb{F}$ and examine the operator $T_1^*T_1 - \lambda I$. We have

$$T_1^*T_1 - \lambda I = S_2^*T_2^*T_2S_2 - \lambda S_2^*S_2 = S_2^*(T_2^*T_2 - \lambda I)S_2.$$

Because both S_2 and S_2^* are unitary operators, $\dim \text{null}(T_2^*T_2 - \lambda I) = \dim \text{null}(S_2^*(T_2^*T_2 - \lambda I)S_2) = \dim \text{null}(T_1^*T_1 - \lambda I)$. By the definition of an eigenspace, $\dim E(\lambda, T_1^*T_1) = \dim E(\lambda, T_2^*T_2)$.

Hence, if λ is an eigenvalue of $T_1^*T_1$, it is also an eigenvalue of $T_2^*T_2$ with the same multiplicity; and if λ is not an eigenvalue of $T_1^*T_1$, it is also not an eigenvalue of $T_2^*T_2$. That implies T_1 and T_2 have the same singular values.

Now suppose T_1 and T_2 have the same singular values s_1, \dots, s_n . Let s_1, \dots, s_m be nonzero singular values. Then there exist such bases e_1, \dots, e_n , f_1, \dots, f_n , g_1, \dots, g_n , and h_1, \dots, h_n that provide singular value decomposition of T_1 and T_2 . Now we have

$$T_1e_k = \begin{cases} s_k f_k, & \text{if } k \leq m, \\ 0, & \text{if } k > m. \end{cases} \quad T_2g_k = \begin{cases} s_k h_k, & \text{if } k \leq m, \\ 0, & \text{if } k > m. \end{cases}$$

Now define operators $S_1, S_2 \in \mathcal{L}(V)$ as

$$S_1h_k = f_k, \quad \text{and} \quad S_2e_k = g_k.$$

Then we have

$$\begin{aligned} S_1 T_2 S_2 e_k &= S_1 T_2 g_k = \begin{cases} S_1(s_k h_k), & \text{if } k \leq m, \\ S_1(0), & \text{if } k > m \end{cases} \\ &= \begin{cases} s_k f_k, & \text{if } k \leq m, \\ 0, & \text{if } k > m \end{cases} \\ &= T_1 e_k. \end{aligned}$$

By the linear map lemma, $T_1 = S_1 T_2 S_2$, which completes the second part of the proof. \square

14 Suppose $T \in \mathcal{L}(V, W)$. Let s_n denote the smallest singular value of T . Prove that $s_n \|v\| \leq \|Tv\|$ for every $v \in V$.

Solution:

If $s_n = 0$, then $s_n \|v\| = 0 \leq \|Tv\|$ because of positivity of norms.

Now let $s_n > 0$. Then we can use singular value decomposition (7.70) with appropriate basis e_1, \dots, e_n of V and an orthonormal list f_1, \dots, f_n in W :

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_n \langle v, e_n \rangle f_n,$$

for every $v \in V$. Then

$$\begin{aligned} \|Tv\|^2 &= s_1^2 |\langle v, e_1 \rangle|^2 + \dots + s_n^2 |\langle v, e_n \rangle|^2 \\ &\geq s_n^2 |\langle v, e_1 \rangle|^2 + \dots + s_n^2 |\langle v, e_n \rangle|^2 \\ &= s_n^2 (|\langle v, e_1 \rangle|^2 + \dots + |\langle v, e_n \rangle|^2) \\ &= s_n^2 \|v\|^2, \end{aligned}$$

where we used Theorem 6.24 in the first equality, and Theorem 6.30 in the last equality. Taking square root on both sides, we arrive at the desired result:

$$s_n \|v\| \leq \|Tv\|,$$

for every $v \in V$. \square

15 Suppose $T \in \mathcal{L}(V)$ and $s_1 \geq \dots \geq s_n$ are the singular values of T . Prove that if λ is an eigenvalue of T , then $s_1 \geq |\lambda| \geq s_n$.

Solution:

Let v be an eigenvector of T with the eigenvalue λ and $\|v\| = 1$. Then $\|Tv\| = |\lambda|$. Applying the result of *Problem 7E.4*, we get the desired relation $s_1 \geq |\lambda| \geq s_n$. \square

16 Suppose $T \in \mathcal{L}(V, W)$. Prove that $(T^*)^\dagger = (T^\dagger)^*$.

Let s_1, \dots, s_m be the positive singular values of T . In *Problem 7E.9* we have shown that T^* has the same singular values as T .

Now let e_1, \dots, e_m and f_1, \dots, f_m be the orthonormal lists in V and W that provide singular value decomposition. For every $w \in W$ we have

$$T^*w = s_1\langle w, f_1 \rangle e_1 + \cdots + s_m\langle w, f_m \rangle e_m.$$

Applying Theorem 7.75 to T^* , we get an expression for $(T^*)^\dagger$

$$(T^*)^\dagger v = \frac{\langle v, e_1 \rangle}{s_1} f_1 + \cdots + \frac{\langle v, e_m \rangle}{s_m} f_m,$$

for every $v \in V$.

Now examine T^\dagger :

$$T^\dagger w = \frac{\langle w, f_1 \rangle}{s_1} e_1 + \cdots + \frac{\langle w, f_m \rangle}{s_m} e_m,$$

for every $w \in W$. By the result of *Problem 7E.8*, $1/s_1, \dots, 1/s_m$ are the positive singular values of T^\dagger . Now applying Theorem 7.75 to it, we get an expression for $(T^\dagger)^*$:

$$(T^\dagger)^* v = \frac{1}{s_1} \langle v, e_1 \rangle f_1 + \cdots + \frac{1}{s_m} \langle v, e_m \rangle f_m,$$

for every $v \in V$.

Thus, we have shown that $(T^*)^\dagger v = (T^\dagger)^* v$ for every $v \in V$, which means $(T^*)^\dagger = (T^\dagger)^*$. \square

17 Suppose $T \in \mathcal{L}(V)$. Prove that T is self-adjoint if and only if T^\dagger is self-adjoint.

Solution:

First, suppose T is self-adjoint. Then

$$(T^\dagger)^* = (T^*)^\dagger = T^\dagger,$$

where we used the result of *Problem 7E.16*. Thus, T is self-adjoint implies T^\dagger is self-adjoint.

Now suppose T^\dagger is self-adjoint. Then

$$T^* = ((T^\dagger)^\dagger)^* = ((T^\dagger)^*)^\dagger = (T^\dagger)^\dagger = T,$$

where we used *Problem 6C.23* in the first and last equalities, and *Problem 7E.16* in the second equality. Thus, T^\dagger is self-adjoint implies T is self-adjoint, completing the second part of the proof. \square

7F Consequences of Singular Value Decomposition

- 1 Prove that if $S, T \in \mathcal{L}(V, W)$, then $|||S|| - ||T||| \leq \|S - T\|$.

Solution:

The definition of $\|S - T\|$ implies that there exists $v_1, v_2 \in V$ such that $\|v_1\|, \|v_2\| \leq 1$, $\|Sv_1\| = \|S\|$, and $\|Tv_2\| = \|T\|$. Now

$$\begin{aligned} |||S|| - ||T||| &= |||Sv_1\| - \|Tv_2\|| \\ &\leq \|Sv_1 - Tv_2\| \\ &= \|(S - T)v_1 + T(v_1 - v_2)\| \\ &\leq \|(S - T)v_1\| + \|T(v_1 - v_2)\| \leq \|(S - T)v_1\| \\ &\leq \|S - T\|, \end{aligned}$$

where the first inequality uses the reverse triangle inequality (*Problem 6A.20*), the second inequality uses the triangle inequality (6.17). That proves the desired result. \square

- 2 Suppose that $T \in \mathcal{L}(V)$ is self-adjoint or that $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is normal. Prove that

$$\|T\| = \max\{|\lambda| : \lambda \text{ is an eigenvalue of } T\}.$$

Solution:

Result of *Problem 7E.7* states that if $\lambda_1, \dots, \lambda_n$ are eigenvalues of T (with repetitions), then singular values of T are $|\lambda_1|, \dots, |\lambda_n|$. By Theorem 7.88, $\|T\|$ equals the largest singular value of T . This, in turn, equals the largest of $|\lambda_1|, \dots, |\lambda_n|$, proving the claimed result. \square

- 3 Suppose $T \in \mathcal{L}(V, W)$ and $v \in V$. Prove that

$$\|Tv\| = \|T\|\|v\| \iff T^*Tv = \|T\|^2v.$$

Solution:

First suppose that $T^*Tv = \|T\|^2v$. Then

$$\begin{aligned} \|Tv\|^2 &= \langle Tv, Tv \rangle \\ &= \langle T^*Tv, v \rangle \\ &= \langle \|T\|^2v, v \rangle = \|T\|^2 \langle v, v \rangle \\ &= \|T\|^2 \|v\|^2. \end{aligned}$$

Taking square root on both sides we get $\|Tv\| = \|T\|\|v\|$.

Now suppose that $\|Tv\| = \|T\|\|v\|$. Note that $\|T\|$ is the largest singular value of T (Theorem 7.88 a), hence $\|T\|^2$ is the largest eigenvalue of T^*T . T^*T is a positive operator (7.64a), and hence is self-adjoint (7.38 b), thus we can use the result of *Problem 7C.13a* to it. We have that $T^*T - \|T\|^2I$ is a positive operator.

Now examine the following:

$$\begin{aligned}\langle (T^*T - \|T\|^2I)v, v \rangle &= \langle T^*Tv, v \rangle - \langle \|T\|^2v, v \rangle \\ &= \langle Tv, Tv \rangle - \|T\|^2\langle v, v \rangle \\ &= \|Tv\|^2 - \|T\|^2\|v\|^2 = 0.\end{aligned}$$

Then, by Theorem 7.43, $(T^*T - \|T\|^2I)v = 0$, or $T^*Tv = \|T\|^2v$, which completes the proof. \square

4 Suppose $T \in \mathcal{L}(V, W)$, $v \in V$, and $\|Tv\| = \|T\|\|v\|$. Prove that if $u \in V$ and $\langle u, v \rangle = 0$, then $\langle Tu, Tv \rangle = 0$.

Solution:

Examine the inner product

$$\langle Tv, Tu \rangle = \langle T^*Tv, u \rangle = \langle \|T\|^2v, u \rangle = \|T\|^2\langle v, u \rangle = 0,$$

where we used the result of the previous problem in the second equality. Now $\langle Tu, Tv \rangle = \overline{\langle Tv, Tu \rangle} = 0$. \square

5 Suppose U is a finite-dimensional inner product space, $T \in \mathcal{L}(V, U)$, and $S \in \mathcal{L}(U, W)$. Prove that

$$\|ST\| \leq \|S\|\|T\|.$$

Solution:

Suppose $v \in V$ is such that $\|v\| \leq 1$ and $\|Tv\| = \|T\|$. Then

$$\|STv\| \leq \|S\|\|Tv\| = \|S\|\|T\|,$$

where the inequality comes from applying Theorem 7.82 to $S(Tv)$ and from Theorem 7.88 (a). \square

6 Prove or give a counterexample: If $S, T \in \mathcal{L}(V)$, then $\|ST\| = \|TS\|$.

Solution:

Let $V = \mathbb{R}$. Consider operators $S, T \in \mathcal{L}(V)$ defined by the following matrices with respect to the standard basis:

$$\mathcal{M}(T) = \begin{pmatrix} 0 & 1 \\ 0 & 2 \end{pmatrix}, \quad \mathcal{M}(S) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Using matrix multiplication, we get

$$\mathcal{M}(TS) = \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, \quad \mathcal{M}(ST) = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

Matrix of ST is diagonal, so we can state $\|ST\| = 1$.

For TS we first need to find singular values. We compute matrix of $(TS)^*TS$

$$\mathcal{M}((TS)^*(TS)) = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix} = \begin{pmatrix} 5 & 0 \\ 0 & 0 \end{pmatrix}.$$

Thus, the singular values of TS are $\sqrt{5}, 0$, and $\|TS\| = \sqrt{5}$.

So we have given S, T such that $\|ST\| \neq \|TS\|$. \square

7 Show that defining $d(S, T) = \|S - T\|$ for $S, T \in \mathcal{L}(V, W)$ makes d a metric on $\mathcal{L}(V, W)$.

Solution:

Taking definition from *Analysis II* by Terence Tao (1.1.2), the metric must satisfy the following axioms (adopted for our case):

- (a) for any $T \in \mathcal{L}(V, W)$, we have $d(T, T) = 0$.
- (b) for any distinct $S, T \in \mathcal{L}(V, W)$, we have $d(S, T) > 0$.
- (c) for any $S, T \in \mathcal{L}(V, W)$, we have $d(S, T) = d(T, S)$.
- (d) for any $S, T, R \in \mathcal{L}(V, W)$, we have $d(S, R) \leq d(S, T) + d(T, R)$.

The axioms (a) and (b) are satisfied due to the basic properties of norms (7.87a and b). Indeed,

$$d(T, T) = \|T - T\| = \|0\| = 0.$$

And for $S \neq T$, we have $d(S, T) = \|S - T\| \geq 0$. If $\|S - T\| = 0$, it implies $S = T$, which is not by our assumption.

Now consider property (c):

$$d(S, T) = \|S - T\| = \|-1(T - S)\| = |-1|\|T - S\| = \|T - S\| = d(T, S),$$

where we use 7.87c in the third equality.

At last, we have

$$\begin{aligned} d(S, T) &= \|S - T\| = \|S - R + R - T\| \\ &\leq \|S - R\| + \|R - T\| \\ &= d(S, R) + d(R, T) \\ &= d(S, R) + d(T, R), \end{aligned}$$

where we used 7.87c applied to $(S - R)$ and $(R - T)$ in the inequality, and used symmetry property of d in the last equality. That concludes the proof that d is a well-defined metric. \square

8 (a) Prove that if $T \in \mathcal{L}(V)$ and $\|I - T\| < 1$, then T is invertible.

(b) Suppose that $S \in \mathcal{L}(V)$ is invertible. Prove that if $T \in \mathcal{L}(V)$ and $\|S - T\| < 1/\|S^{-1}\|$, then T is invertible.

Solution:

Suppose T is a non-invertible operator and $\|I - T\| < 1$. That means for every $v \in V$

$$\|(I - T)v\| \leq \|I - T\|\|v\| < \|v\|. \quad (7.13)$$

As T is non-invertible, there exists $u \in V, u \neq 0$ such that $Tu = 0$ (Theorem 3.63). We have

$$\|(I - T)u\| = \|u - Tu\| = \|u - 0\| = \|u\|,$$

which contradicts eq. 7.13. Thus, T must be an invertible operator. \square

(b) Suppose T is a non-invertible operator. Then there exists $v \in V, v \neq 0$ such that $Tv = 0$ (Theorem 3.63). Examine the following

$$\begin{aligned} \|v\| &= \|S^{-1}Sv\| \leq \|S^{-1}\|\|Sv\| = \|S^{-1}\|\|(S - T)v\| \\ &\leq \|S^{-1}\|\|S - T\|\|v\| < \|S^{-1}\|\frac{1}{\|S^{-1}\|}\|v\| \\ &< \|v\|. \end{aligned}$$

We obtained the false inequality $\|v\| < \|v\|$, which shows that assumption about T being non-invertible is also false. Thus, T must be invertible. \square

9 Suppose $T \in \mathcal{L}(V)$. Prove that for every $\epsilon > 0$, there exists an invertible operator $S \in \mathcal{L}(V)$ such that $0 < \|T - S\| < \epsilon$.

Solution:

Let e_1, \dots, e_m and f_1, \dots, f_m be orthonormal lists in V that provide singular value decomposition of T (Theorem 7.70). Extend these lists to orthonormal bases e_1, \dots, e_n and f_1, \dots, f_n of V . Now for every $v \in V$ we can write

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_n \langle v, e_n \rangle f_n.$$

Let $s_{l+1} = \dots = s_n$ be the smallest singular values of T . If T is not invertible, then $l = m$, and $s_{l+1} = \dots = s_n = 0$, but this will not change the rest of the proof.

For any given $\epsilon > 0$, define an invertible operator $S \in \mathcal{L}(V)$ as follows

$$Sv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_l \langle v, e_l \rangle f_l + (s_{l+1} + \epsilon/2) \langle v, e_{l+1} \rangle f_{l+1} + \dots + (s_n + \epsilon/2) \langle v, e_n \rangle f_n.$$

Note that positivity of ϵ ensures S is invertible operator (Theorem 7.68a).

Now we get that the operator $S - T$ acts as

$$(S - T)v = \epsilon/2 \langle v, e_{l+1} \rangle f_{l+1} + \dots + \epsilon/2 \langle v, e_n \rangle f_n.$$

This expression provides a singular value decomposition of $S - T$ (see *Problem 7E.8*). Thus, $S - T$ has the only singular value, $\epsilon/2 > 0$. Hence, by Theorem 7.88, $\|T - S\| = \|S - T\| = \epsilon/2$.

Thus, S is an invertible operator such that $0 < \|T - S\| < \epsilon$. \square

10 Suppose $\dim V > 1$ and $T \in \mathcal{L}(V)$ is not invertible. Prove that for every $\epsilon > 0$, there exists $S \in \mathcal{L}(V)$ such that $0 < \|T - S\| < \epsilon$ and S is not invertible.

Solution:

Suppose s_1, \dots, s_m are the positive singular values of T , e_1, \dots, e_m and f_1, \dots, f_m are orthonormal lists in V that provide singular value decomposition of T :

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_m \langle v, e_m \rangle f_m.$$

Suppose $s_{l+1} = \dots = s_m$ are the smallest positive singular values of T . Then define S as

$$Sv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_l \langle v, e_l \rangle f_l + (s_{l+1} + \epsilon/2) \langle v, e_{l+1} \rangle f_{l+1} + \dots + (s_m + \epsilon/2) \langle v, e_m \rangle f_m.$$

Note, that $\dim \text{range } S < \dim V$, so S is not invertible. Then, like in the previous exercise, we have $\|T - S\| = \epsilon/2$.

Hence, S is not invertible operator such that $0 < \|T - S\| < \epsilon$. \square

11 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$. Prove that for every $\epsilon > 0$ there exists a diagonalizable operator $S \in \mathcal{L}(V)$ such that $0 < \|T - S\| < \epsilon$.

Solution:

By Theorem 5.47, there exists a basis e_1, \dots, e_n of V , with respect to which the matrix of T is upper-triangular. Let $\lambda_1, \dots, \lambda_n$ be the diagonal elements of $\mathcal{M}(T)$.

For any given $\epsilon > 0$ define S via $Se_j = (\lambda_j - \epsilon/2)e_j$. By construction, S is diagonalizable with respect to the basis e_1, \dots, e_n . Note that matrix of $T - S$ has the form

$$\mathcal{M}(T - S) = \begin{pmatrix} \epsilon/2 & & * \\ & \ddots & \\ 0 & & \epsilon/2 \end{pmatrix}$$

Thus, $T - S$ is upper-triangularizable and its only eigenvalue is $\epsilon/2$ (repeated n times). As $\epsilon/2 > 0$, the singular values of $T - S$ are $\epsilon/2, \dots, \epsilon/2$ (n times) by the result of *Problem 7E.7*. Now, Theorem 7.88 implies that $\|T - S\| = \epsilon/2 < \epsilon$. So we have shown that for every T over a complex vector space and for every $\epsilon > 0$ there exists a diagonalizable operator S such that $0 < \|T - S\| < \epsilon$. \square

12 Suppose $T \in \mathcal{L}(V)$ is a positive operator. Shows that $\|\sqrt{T}\| = \sqrt{\|T\|}$.

Solution:

T is a positive operator, hence all its eigenvalues are non-negative and it has a positive square root (Theorem 7.38). Suppose, zero is the largest eigenvalue of T . Then $T = 0$ and $\sqrt{T} = 0$. Naturally, $\|\sqrt{T}\| = \sqrt{\|T\|} = 0$.

Let $\lambda_1, \dots, \lambda_n$ be the eigenvalues of T , with $\lambda_1 > 0$ being the largest, so $\|T\| = \lambda_1$. Then the eigenvalues of \sqrt{T} are $\sqrt{\lambda_1}, \dots, \sqrt{\lambda_n}$. The largest eigenvalue of \sqrt{T} is $\sqrt{\lambda_1}$, so $\|\sqrt{T}\| = \sqrt{\lambda_1} = \sqrt{\|T\|}$. \square

13 Suppose $S, T \in \mathcal{L}(V)$ are positive operators. Show that

$$\|S - T\| \leq \max\{\|S\|, \|T\|\} \leq \|S + T\|.$$

Solution:

Without loss of generality, let $\|S\| \geq \|T\|$. Otherwise, change roles of T and S , because $\|S - T\| = \|T - S\|$.

Consider the operator $\|S\|I - (S - T) = (\|S\|I - S) + T$. This operator is positive being the sum of two positive operators. Indeed for any $v \in V$

$$\langle (\|S\|I - S)v, v \rangle = \|S\|\langle v, v \rangle - \langle Sv, v \rangle \geq \|S\|\|v\|^2 - \|S\|\|v\|^2 = 0.$$

The inequality above comes from $\langle Sv, v \rangle \leq \|S\| \langle v, v \rangle$. Indeed, if v_1, \dots, v_n is the orthonormal basis of V consisting of eigenvectors of S (Theorem 7.38), and $v = a_1 v_1 + \dots + a_n v_n$, then

$$\begin{aligned}
 \langle Sv, v \rangle &= \langle S(a_1 v_1 + \dots + a_n v_n), v \rangle \\
 &= \langle a_1 S v_1 + \dots + a_n S v_n, a_1 v_1 + \dots + a_n v_n \rangle \\
 &= \langle a_1 \lambda_1 v_1 + \dots + a_n \lambda_n v_n, a_1 v_1 + \dots + a_n v_n \rangle \\
 &= \lambda_1 |a_1|^2 + \dots + \lambda_n |a_n|^2 \\
 &\leq \lambda \|v\|^2 \\
 &= \|S\| \|v\|^2,
 \end{aligned} \tag{7.14}$$

where λ is the largest eigenvalue of S and hence its norm (see *Problem 7F.2*).

There exists an orthonormal basis of V , with respect to which the matrix of $\|S\|I - (S - T)$ is diagonalizable with non-negative diagonal entries. As $\|S\|I$ has diagonal matrix with respect to any basis, $S - T$ is diagonalizable with respect to the same basis as $\|S\|I - (S - T)$. Taking the diagonal entry corresponding to $\|S - T\|$, we get the desired result $\|S\| - \|S - T\| \geq 0$, or $\|S - T\| \leq \|S\|$.

Now we prove the second part of the problem. Take a normalized eigenvector of S , v , corresponding to the largest eigenvalue. Then

$$\|S\| = \langle Sv, v \rangle \leq \langle Sv, v \rangle + \langle Tv, v \rangle = \langle (S + T)v, v \rangle \leq \|S + T\|,$$

where we used eq. 7.14 applied to the operator $(S + T)$ for the last inequality. \square

14 Suppose U and W are subspaces of V such that $\|P_U - P_W\| < 1$. Prove that $\dim U = \dim W$.

Solution:

Suppose $\dim U \neq \dim W$. Without loss of generality let $\dim U > \dim W$. Denote $\dim U$ by n and $\dim W$ by p .

Singular values of U are 1 (n times) and 0 ($\dim V - n$ times). By Theorem 7.92, $\min\{\|P_U - S\| : S \in \mathcal{L}(V) \text{ and } \dim \text{range } S \leq p\} = s_{p+1}$. As $p < \dim U$, $p + 1$ at most equals $\dim U$, which implies $s_{p+1} = 1$ in any case. Thus, $\|P_U - P_W\| \geq 1$.

That implies if $\|P_U - P_W\| < 1$, then $\dim U = \dim W$, as desired. \square

15 Define $T \in \mathcal{L}(\mathbb{F}^3)$ by

$$T(z_1, z_2, z_3) = (z_3, 2z_1, 3z_2).$$

Find (explicitly) a unitary operator $S \in \mathcal{L}(\mathbb{F}^3)$ such that $T = S\sqrt{T^*T}$.

Solution:

Matrix of T with respect to the standard basis of \mathbb{F}^3 is

$$\mathcal{M}(T) = \begin{pmatrix} 0 & 0 & 1 \\ 2 & 0 & 0 \\ 0 & 3 & 0 \end{pmatrix}.$$

The matrix of T^* is then (Theorem 7.9)

$$\mathcal{M}(T^*) = \begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 3 \\ 1 & 0 & 0 \end{pmatrix}.$$

Then we can find T^*T :

$$\mathcal{M}(T^*T) = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

The matrix of $\sqrt{T^*T}$ is also diagonal, with 2, 3 and 1 as diagonal elements.

A unitary operator can be found as $S = T(\sqrt{T^*T})^{-1}$. The inverse of $\sqrt{T^*T}$ can be found with the result of *Problem 5A.21*. Now

$$\begin{aligned} \mathcal{M}(S) &= \mathcal{M}(T) \cdot \mathcal{M}((\sqrt{T^*T})^{-1}) = \begin{pmatrix} 0 & 0 & 1 \\ 2 & 0 & 0 \\ 0 & 3 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1/2 & 0 & 0 \\ 0 & 1/3 & 0 \\ 0 & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \end{aligned}$$

So, $S(z_1, z_2, z_3) = (z_3, z_1, z_2)$. \square

16 Suppose $S \in \mathcal{L}(V)$ is a positive invertible operator. Prove that there exists $\delta > 0$ such that T is a positive operator for every self-adjoint operator $T \in \mathcal{L}(V)$ with $\|S - T\| < \delta$.

Solution:

As both S and T are self-adjoint, so $S - T$ too: $(S - T)^* = S^* - T^* = S - T$.

Let $v \in V$ is such that $\|v\| = 1$. Then, by 7.14,

$$\langle (S - T)v, v \rangle \leq \|S - T\|. \quad (7.15)$$

On the other hand we have

$$\langle (S - T)v, v \rangle = \langle Sv, v \rangle - \langle Tv, v \rangle. \quad (7.16)$$

Combining eqs. 7.15 and 7.16, we get

$$\langle Tv, v \rangle \geq \langle Sv, v \rangle - \|S - T\|.$$

Now examine S . Let $\lambda_1, \dots, \lambda_n$ be its eigenvalues with corresponding orthonormal eigenvectors e_1, \dots, e_n provided by the Spectral Theorem. Suppose λ_1 is the smallest eigenvalue of S . Then for $v \in V, \|v\| = 1$

$$\begin{aligned} \langle Sv, v \rangle &= \langle S(a_1e_1 + \dots + a_ne_n), a_1e_1 + \dots + a_ne_n \rangle \\ &= \langle a_1\lambda_1e_1 + \dots + a_n\lambda_ne_n, a_1e_1 + \dots + a_ne_n \rangle \\ &= \lambda_1|a_1|^2 + \dots + \lambda_n|a_n|^2 \\ &\geq \lambda_1|a_1|^2 + \dots + \lambda_1|a_n|^2 \\ &= \lambda_1. \end{aligned}$$

This result implies

$$\langle Tv, v \rangle \geq \lambda_1 - \|S - T\|.$$

As S is invertible, $\lambda_1 > 0$, hence we can choose $\delta \leq \lambda_1$ that will guarantee that T is a positive operator. \square

17 Prove that if $u \in V$ and ϕ_u is the linear functional on V defined by the equation $\phi_u(v) = \langle v, u \rangle$, then $\|\phi_u\| = \|u\|$.

Solution:

We can use formula from Theorem 7.88b to examine the norm of ϕ_u .

$$\|\phi_u\| = \max\{|\phi_u(v)| : v \in V \text{ and } \|v\| = 1\}.$$

Using Cauchy-Schwarz inequality we get

$$|\phi_u(v)| = |\langle v, u \rangle| \leq \|v\|\|u\| = \|u\|.$$

This shows that $|\phi_u(v)|$ is at most $\|u\|$. Now we need to show that this value is attainable. Take $v = u/\|u\|$. Then

$$|\phi_u(v)| = |\langle \frac{u}{\|u\|}, v \rangle| = \frac{1}{\|u\|} \langle u, u \rangle = \frac{1}{\|u\|} \|u\|^2 = \|u\|.$$

Hence, $\|\phi_u\| = \|u\|$. \square

18 Suppose e_1, \dots, e_n is an orthonormal basis of V and $T \in \mathcal{L}(V, W)$.

- (a) Prove that $\max\{\|Te_1\|, \dots, \|Te_n\|\} \leq \|T\| \leq (\|Te_1\|^2 + \dots + \|Te_n\|^2)^{1/2}$.
 (b) Prove that $\|T\| = (\|Te_1\|^2 + \dots + \|Te_n\|^2)^{1/2}$ if and only if $\dim \text{range } T \leq 1$.

Solution:

(a) First inequality follows directly from Theorem 7.88b. For the second inequality we can use the result of *Problem 7E.11*. Let s_1, \dots, s_n be the singular values of T . Then

$$(\|Te_1\|^2 + \dots + \|Te_n\|^2)^{1/2} = (s_1^2 + \dots + s_n^2)^{1/2} \geq (s_1^2)^{1/2} = s_1 = \|T\|,$$

which completes the second part of the proof.

(b) By the Theorem 7.68, the number of positive singular values of T equals $\dim \text{range } T$. Note that $s_1^2 + \dots + s_n^2 = s_1^2$ if and only if all $s_2 = \dots = s_n = 0$, so T must have at most one non-zero singular value, which means $\dim \text{range } T \leq 1$. \square

19 Prove that if $T \in \mathcal{L}(V, W)$, then $\|T^*T\| = \|T\|^2$.

Solution:

As T^*T is a positive operator on V (Theorem 7.64), it has non-negative eigenvalues $\lambda_1, \dots, \lambda_n$ (let λ_1 be the largest of them). By the result of *Problem 7E.7*, the largest singular value of T^*T is λ_1 , which means $\|T^*T\| = \lambda_1$ (see Theorem 7.88a).

Now, by the definition of singular values, the largest singular value of T is $\sqrt{\lambda_1}$, which equals $\|T\|$. Thus, we have the desired result $\|T^*T\| = \|T\|^2$. \square

20 Suppose $T \in \mathcal{L}(V)$ is normal. Prove that $\|T^k\| = \|T\|^k$ for every positive integer k .

Solution:

$\|T\|$ equals the largest singular value of T (Theorem 7.88), which in turn equals the square root of the largest eigenvalue of T^*T .

As T^*T is a self-adjoint operator, there exists an orthonormal basis consisting of eigenvectors of T^*T . Note that for each eigenvector e_j with the corresponding eigenvalue λ_j , we have

$$(T^*T)^k e_j = \lambda_j^k e_j,$$

for every positive integer k . That means if $\lambda_1, \dots, \lambda_n$ are eigenvalues of T^*T , then $\lambda_1^k, \dots, \lambda_n^k$ are eigenvalues of $(T^*T)^k$. That implies if λ is the largest eigenvalue of T^*T , then λ^k is the largest eigenvalue of $(T^*T)^k$.

Now consider T^k . Its norm, like in the case of T , equals the square root of the largest eigenvalue of $(T^k)^*T^k$. Using definition of a normal operator (T and T^* commute), we have

$$(T^k)^*T^k = (T^*)^kT^k = (T^*T)^k.$$

Therefore, the largest eigenvalue of $(T^k)^*T^k$ is the largest eigenvalue of $(T^*T)^k$, which equals λ^k , where λ is the largest eigenvalue of T . That implies the desired result $\|T^k\| = \|T\|^k$. \square

21 Suppose $\dim V > 1$ and $\dim W > 1$. Prove that the norm on $\mathcal{L}(V, W)$ does not come from an inner product. In other words, prove that there does not exist an inner product on $\mathcal{L}(V, W)$ such that

$$\max\{\|Tv\| : v \in V \text{ and } \|v\| \leq 1\} = \sqrt{\langle T, T \rangle}$$

for all $T \in \mathcal{L}(V, W)$.

Solution:

Let v_1, \dots, v_n be an orthonormal basis of V and w_1, \dots, w_m be an orthonormal basis of W . Define $T, S \in \mathcal{L}(V, W)$ as follows:

$$\begin{aligned} Tv_1 &= w_1, & Tv_2 &= w_2, & Tv_j &= 0 \text{ for } j > 2, \\ Sv_1 &= w_1, & Sv_2 &= -w_2, & Sv_j &= 0 \text{ for } j > 2. \end{aligned}$$

We have $\|T\| = \|S\| = 1$. Now consider $T + S$ and $T - S$:

$$\begin{aligned} (T + S)v_1 &= 2w_1, & (T + S)v_2 &= 0, & Tv_j &= 0 \text{ for } j > 2, \\ (T - S)v_1 &= 0, & (T - S)v_2 &= 2w_2, & Tv_j &= 0 \text{ for } j > 2. \end{aligned}$$

Hence, $\|T + S\| = \|T - S\| = 2$. If the norm comes from an inner product, it must satisfy the parallelogram equality (6.21). We have

$$\|T + S\|^2 + \|T - S\|^2 = 2^2 + 2^2 = 8 \neq 2(\|T\|^2 + \|S\|^2) = 2(1 + 1) = 4.$$

Thus, the norm on $\mathcal{L}(V, W)$ does not come from an inner product. \square

22 Suppose $T \in \mathcal{L}(V, W)$. Let $n = \dim V$ and let $s_1 \geq \dots \geq s_n$ denote the singular values of T . Prove that if $1 \leq k \leq n$, then

$$\min\{\|T|_U\| : U \text{ is a subspace of } V \text{ with } \dim U = k\} = s_{n-k+1}.$$

23 Suppose $T \in \mathcal{L}(V, W)$. Show that T is uniformly continuous with respect to the metrics on V and W that arise from the norms on those spaces.

24 Suppose $T \in \mathcal{L}(V)$ is invertible. Prove that

$$\|T^{-1}\| = \|T\|^{-1} \iff \frac{T}{\|T\|} \text{ is a unitary operator.}$$

Solution:

Suppose s_1, \dots, s_n are singular values of T . Then the singular values of T^{-1} are $1/s_n, \dots, 1/s_1$, by the result of *Problem 7E.10*. So, $\|T\| = s_1$ and $\|T^{-1}\| = 1/s_n$. That implies $\|T^{-1}\| = \|T\|^{-1}$ if and only if $s_1 = s_n$ (and hence all other singular values).

Let e_1, \dots, e_n and f_1, \dots, f_n be orthonormal bases of V such that

$$Te_j = s_j f_j.$$

If all singular values of T are equal, then all of them are $\|T\|$. Then

$$\frac{T}{\|T\|} e_j = \frac{1}{\|T\|} \|T\| f_j = f_j,$$

which by Theorem 7.53 implies that $T/\|T\|$ is a unitary operator.

On the other hand, if $T/\|T\|$ is a unitary operator, then for an orthonormal basis e_1, \dots, e_n of V , we have that

$$\frac{T}{\|T\|} e_j = f_j,$$

where f_1, \dots, f_n is also an orthonormal basis of V . On the other hand,

$$\frac{T}{\|T\|} e_j = \frac{1}{\|T\|} (Te_j),$$

hence $Te_j = \|T\| f_j$. That provides a singular value decomposition of T (see *Problem 7E.8*), and thus all singular values of T equal $\|T\|$, which means $\|T^{-1}\| = \|T\|^{-1}$, which completes the proof. \square

25 Fix $u, x \in V$ with $u \neq 0$. Define $T \in \mathcal{L}(V)$ by $Tv = \langle v, u \rangle x$ for every $v \in V$. Prove that

$$\sqrt{T^*T}v = \frac{\|x\|}{\|u\|} \langle v, u \rangle u$$

for every $v \in V$.

Solution:

Let $e_1 = u/\|u\|$ and $f_1 = x/\|x\|$. Then

$$Tv = \langle v, u \rangle x = \|u\| \|x\| \langle v, e_1 \rangle f_1,$$

which provides singular value decomposition for T .

Following the proof of Theorem 7.93, we have

$$\sqrt{T^*T}v = s_1\langle v, e_1\rangle e_1 = \|u\|\|x\|\langle v, \frac{u}{\|u\|}\rangle \frac{u}{\|u\|} = \frac{\|x\|}{\|u\|}\langle v, u\rangle u,$$

which completes the proof. \square

26 Suppose $T \in \mathcal{L}(V)$. Prove that T is invertible if and only if there exists a unique unitary operator $S \in \mathcal{L}(V)$ such that $T = S\sqrt{T^*T}$.

Solution:

First, suppose T is invertible. That means T^* is invertible (Theorem 7.5), and hence T^*T is invertible (*Problem 3D.2*). This implies $\sqrt{T^*T}$ is invertible (as follows from *Problem 7C.16*). Now if we consider polar decomposition $T = S\sqrt{T^*T}$, then we can write S as

$$S = T\sqrt{T^*T}^{-1}.$$

Because, $\sqrt{T^*T}$ is uniquely determined (Theorem 7.39), S is a unique unitary operator.

We will prove the other direction by contrapositive. Suppose T is not invertible. That means there is at least one zero singular value of T (Theorem 7.68). Let $s_n = 0$. Then, following proof of Theorem 7.93, we construct two unitary operators:

$$\begin{aligned} S_1 &= \langle v, e_1\rangle f_1 + \cdots + \langle v, e_{n-1}\rangle f_{n-1} + \langle v, e_n\rangle f_n, \\ S_2 &= \langle v, e_1\rangle f_1 + \cdots + \langle v, e_{n-1}\rangle f_{n-1} - \langle v, e_n\rangle f_n. \end{aligned}$$

Here, s_1, \dots, s_m are positive singular values of T ($m < n$), e_1, \dots, e_m and f_1, \dots, f_m are orthonormal lists that provide SVD of T , e_1, \dots, e_n and f_1, \dots, f_n are those lists extended to the orthonormal bases.

Apply S_1 and S_2 to $\sqrt{T^*T}v$, where $v \in V$. We have

$$\begin{aligned} S_1\sqrt{T^*T}v &= S_1(s_1\langle v, e_1\rangle e_1 + \cdots + s_m\langle v, e_m\rangle e_m) \\ &= s_1\langle v, e_1\rangle f_1 + \cdots + s_m\langle v, e_m\rangle f_m = Tv, \end{aligned}$$

and

$$\begin{aligned} S_2\sqrt{T^*T}v &= S_2(s_1\langle v, e_1\rangle e_1 + \cdots + s_m\langle v, e_m\rangle e_m) \\ &= s_1\langle v, e_1\rangle f_1 + \cdots + s_m\langle v, e_m\rangle f_m = Tv. \end{aligned}$$

Thus, T is not invertible implies S in the polar decomposition is not uniquely determined. That is equivalent to S being unique implies that T is invertible, which completes the proof. \square

27 Suppose $T \in \mathcal{L}(V)$ and s_1, \dots, s_n are the singular values of T . Let e_1, \dots, e_n and f_1, \dots, f_n be orthonormal bases of V such that

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \cdots + s_n \langle v, e_n \rangle f_n$$

for all $v \in V$. Define $S \in \mathcal{L}(V)$ by

$$Sv = \langle v, e_1 \rangle f_1 + \cdots + \langle v, e_n \rangle f_n.$$

(a) Show that S is unitary and $\|T - S\| = \max\{|s_1 - 1|, \dots, |s_n - 1|\}$.

(b) Show that if $E \in \mathcal{L}(V)$ is unitary, then $\|T - E\| \geq \|T - S\|$.

Solution:

(a) Note that for every e_j in the basis of V , we have $Se_j = \langle e_j, e_j \rangle f_j = f_j$. Hence Se_1, \dots, Se_n is an orthonormal basis of V , which by Theorem 7.53 implies that S is unitary.

Now examine $T - S$:

$$(T - S)v = (s_1 - 1)\langle v, e_1 \rangle f_1 + \cdots + (s_n - 1)\langle v, e_n \rangle f_n.$$

Now define an orthonormal basis w_1, \dots, w_n of V as follows: $w_j = f_j$ if $s_j - 1 \geq 0$, and $w_j = -f_j$ otherwise. Then

$$(T - S)v = |s_1 - 1|\langle v, e_1 \rangle w_1 + \cdots + |s_n - 1|\langle v, e_n \rangle w_n.$$

By the result of *Problem 7E.8*, $|s_1 - 1|, \dots, |s_n - 1|$ are the singular values of $T - S$. By the definition of a norm of a linear map, $\|T - S\| = \max\{|s_1 - 1|, \dots, |s_n - 1|\}$.

(b) Consider $(T - E)e_j$, where e_j is a vector from an orthonormal basis of V defined in (a).

$$\|T - E\| \geq \|(T - E)e_j\| = \|Te_j - Ee_j\| \geq \||Te_j\| - \|Ee_j\|| = |s_j - 1|,$$

where we used the reverse triangle inequality (*Problem 6A.20*) in the second inequality, and unitarity of E in $\|Ee_j\| = \|e_j\| = 1$. This shows that $\|T - E\|$ is greater or equal than any $|s_j - 1|$, where s_1, \dots, s_n are singular values of T , which by the result of part (a) implies

$$\|T - E\| \geq \|T - S\|. \quad \square$$

28 Suppose $T \in \mathcal{L}(V)$. Prove that there exists a unitary operator $S \in \mathcal{L}(V)$ such that $T = \sqrt{TT^*}S$.

Solution:

Let s_1, \dots, s_m be the positive singular values of T , and let e_1, \dots, e_m and f_1, \dots, f_m be orthonormal lists in V such that

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_m \langle v, e_m \rangle f_m$$

for every $v \in V$. Extend e_1, \dots, e_m and f_1, \dots, f_m to orthonormal bases e_1, \dots, e_n and f_1, \dots, f_n of V .

Define $S \in \mathcal{L}(V)$ by

$$Sv = \langle v, e_1 \rangle f_1 + \dots + \langle v, e_n \rangle f_n,$$

for each $v \in V$. Then

$$\|Sv\|^2 = \|\langle v, e_1 \rangle f_1 + \dots + \langle v, e_n \rangle f_n\|^2 = |\langle v, e_1 \rangle|^2 + \dots + |\langle v, e_n \rangle|^2 = \|v\|^2.$$

Thus, S is a unitary operator.

Using the result of *Problem 7E.8*, we have

$$TT^*v = s_1^2 \langle v, f_1 \rangle f_1 + \dots + s_m^2 \langle v, f_m \rangle f_m,$$

for every $v \in V$. Thus if $v \in V$, then

$$\sqrt{TT^*}v = s_1 \langle v, f_1 \rangle f_1 + \dots + s_m \langle v, f_m \rangle f_m,$$

because the operator that sends v to the right side of the equation above is a positive operator whose square equals T^*T . Now

$$\begin{aligned} \sqrt{TT^*}Sv &= \sqrt{TT^*}(\langle v, e_1 \rangle f_1 + \dots + \langle v, e_n \rangle f_n) \\ &= \langle v, e_1 \rangle \sqrt{TT^*}f_1 + \dots + \langle v, e_n \rangle \sqrt{TT^*}f_n \\ &= s_1 \langle v, e_1 \rangle f_1 + \dots + s_m \langle v, e_n \rangle f_n \\ &= Tv, \end{aligned}$$

where the last equation comes from the singular value decomposition of T . Thus, $T = \sqrt{TT^*}S$. \square

29 Suppose $T \in \mathcal{L}(V)$.

- (a) Use the polar decomposition to show that there exists a unitary operator $S \in \mathcal{L}(V)$ such that $TT^* = ST^*TS^*$.

(b) Show how (a) implies that T and T^* have the same singular values.

Solution:

(a) There exists a unitary operator $S \in \mathcal{L}(V)$ such that $T = S\sqrt{T^*T}$, see Theorem 7.93. Then, $T^* = (S\sqrt{T^*T})^* = (\sqrt{T^*T})^*S^* = \sqrt{T^*T}S^*$, where the last equality is true, because T^*T is a positive operator (Theorem 7.64), hence its square root $\sqrt{T^*T}$ is a self-adjoint operator (Theorem 7.38). Now we have

$$TT^* = S\sqrt{T^*T}\sqrt{T^*T}S^* = ST^*TS^*,$$

as desired. \square

(b) Result of the part (a) along with *Problem 7E.13* implies that TT^* and T^*T have the same singular values.

Note, that the singular values of TT^* and T^*T are also the eigenvalues of these operators (both of them are positive). Now, by the definition, the singular values of T are non-negative square roots of T^*T , while the singular values of T^* are non-negative square roots of $(T^*)^*T^* = TT^*$. Thus, the singular values of T and T^* are the same. \square

30 Suppose $T \in \mathcal{L}(V)$, $S \in \mathcal{L}(V)$ is a unitary operator, and $R \in \mathcal{L}(V)$ is a positive operator such that $T = SR$. Prove that $R = \sqrt{T^*T}$.

Solution:

Consider T^*T :

$$T^*T = (SR)^*SR = R^*S^*SR = R^*R,$$

where the second equality comes from the properties of an adjoint (7.5), and the third equality comes from Theorem 7.53. As R is a positive operator, it is also self-adjoint (Theorem 7.38), hence $T^*T = R^2$, so R is a positive square root of T^*T . Now, T^*T is also a positive operator (Theorem 7.64), therefore its positive square root is unique (Theorem 7.39). That means if $T = SR$, then $R = \sqrt{T^*T}$, as desired. \square

31 Suppose $\mathbb{F} = \mathbb{C}$ and $T \in \mathcal{L}(V)$ is normal. Prove that there exists a unitary operator $S \in \mathcal{L}(V)$ such that $T = S\sqrt{T^*T}$ and such that S and $\sqrt{T^*T}$ both have diagonal matrices with respect to the same orthonormal basis of V .

Solution:

Suppose e_1, \dots, e_n is an orthonormal basis of V that diagonalizes T (Theorem 7.31). For every $v \in V$ we have

$$Tv = \lambda_1 \langle v, e_1 \rangle e_1 + \dots + \lambda_n \langle v, e_n \rangle e_n, \quad (7.17)$$

where $\lambda_1, \dots, \lambda_n$ are the eigenvalues of T . Now, the singular values of T are $|\lambda_1|, \dots, |\lambda_n|$ (in decreasing order), by *Problem 7E.7*.

Define $\alpha_j = \lambda_j/|\lambda_j|$ for each $j = 1, \dots, n$. Then let $f_j = \alpha_j e_j$ for each $j = 1, \dots, n$; note $\|f_j\| = 1$. That transforms 7.17 into

$$Tv = s_1 \langle v, e_1 \rangle f_1 + \dots + s_n \langle v, e_n \rangle f_n,$$

which provides a singular value decomposition of T .

Now the proof of Theorem 7.93 gives us a way to construct S , such that $T = S\sqrt{T^*T}$, in terms of e_1, \dots, e_n and f_1, \dots, f_n .

$\sqrt{T^*T}$ is trivially diagonalizable with respect to the basis e_1, \dots, e_n :

$$\sqrt{T^*T}e_j = s_j e_j.$$

For S we have:

$$Se_j = f_j = \frac{\lambda_j}{|\lambda_j|} e_j,$$

hence it is also diagonalizable with respect to the orthonormal basis e_1, \dots, e_n , which completes the proof. \square

32 Suppose that $T \in \mathcal{L}(V, W)$ and $T \neq 0$. Let s_1, \dots, s_m denote the positive singular values of T . Show that there exists an orthonormal basis e_1, \dots, e_m of $(\text{null } T)^\perp$ such that

$$T \left(E \left(\frac{e_1}{s_1}, \dots, \frac{e_m}{s_m} \right) \right)$$

equals the ball in $\text{range } T$ of radius 1 centered at 0.

Solution:

Let e_1, \dots, e_m and f_1, \dots, f_m be orthonormal lists in V and W , respectively, that provide the singular value decomposition of T (Theorem 7.70). Let $U = \text{span}(e_1, \dots, e_m)$; naturally, e_1, \dots, e_m is an orthonormal basis of U .

Suppose U is not $(\text{null } T)^\perp$. Take any $w \in \text{null } T$, then for some $k \in \{1, \dots, n\}$ the inner product $\langle w, e_k \rangle$ is non-zero. That makes

$$Tw = s_k \langle w, e_k \rangle f_k + \dots \neq 0,$$

which contradicts w being an element of $\text{null } T$ (as f_1, \dots, f_m are linearly independent we care for only one coefficient before f_j being non-zero). Thus, $U = (\text{null } T)^\perp$.

We have:

$$E \left(\frac{e_1}{s_1}, \dots, \frac{e_m}{s_m} \right) = \{v \in V : s_1^2 |\langle v, e_1 \rangle|^2 + \dots + s_m^2 |\langle v, e_m \rangle|^2 < 1\}.$$

Now applying T to v in that ellipse, we have

$$\begin{aligned}\|Tv\|^2 &= \|s_1\langle v, e_1 \rangle f_1 + \cdots + s_m\langle v, e_m \rangle f_m\|^2 \\ &= s_1^2 |\langle v, e_1 \rangle|^2 + \cdots + s_m |\langle v, e_m \rangle|^2 \\ &< 1,\end{aligned}$$

where the last inequality comes from the definition of the ellipse. That implies

$$T\left(E\left(\frac{e_1}{s_1}, \dots, \frac{e_m}{s_m}\right)\right)$$

equals the ball in range T of radius 1 centered at 0. \square
